The time has arrived when it behooves the medical practitioner to awaken from his state of lethargy. No matter where he is located, in the city, village or hamlet, the antituberculosis movement will reach him, and if he is not competent to participate, he will be relegated to the rear rank. There is one great reason why the general practitioner should attain the highest degree of scientific acumen and skill in the diagnosis of the disease, and that is the supreme importance of its early recognition. The necessity for taking timely precautions to prevent infection can hardly be overestimated, nor can the omission to urge such precautions, on the part of the physician, by reason of ignorance or otherwise, be too severely condemned. When we take into consideration that where no precautions are observed, one-seventh of all deaths are due to tuberculosis, and that the infectious character of the disease is clearly established, we cannot else but recognize the responsibility resting upon those who are the guardians of health, both public and private. In short, the practitioner who does not instruct his patients how to care for themselves for their own protection as well as for the safety of those about them, and impress upon them the immense importance of observing those preventive measures, is to say the least culpable in the highest degree if not positively guilty of criminal negligence.

To inaugurate a substantial reform in the sanitary management of tuberculosis will require a radical change in the ethical relations that now exist between the patient and the physician in whose care he has placed himself for advice and treatment. The cruel deception which is usually practiced upon the poor unfortunates must cease and give way to candor, truth and honesty. As soon as pulmonary tuberculosis is found to exist, the fact should be communicated to the patient, and he should not be compelled to remain in ignorance of the true character of his malady. It is a frequent occurrence that the patient's friends will interview the physician before he examines the patient, and charge him particularly not to inform the patient that he has tuberculosis if he finds such to be the case. The request is usually heeded, and his disease is named chronic pneumonia or some other euphemism, and the deception is continued until death claims its victim. It would seem justifiable to mislead these individuals when we consider that in the estimation of the public a positive diagnosis of consumption is equivalent to a death sentence. This being the case the knowledge of the fact is liable to plunge the sufferer into utter despair or else—as it frequently happens—he "turns down" his medical attendant and seeks relief at the hands of the charlatan or wherever hope is extended to him. In view of these facts, it is important that the laity should be taught that tuberculosis is *not* incurable: That under the new régime of hygenic and out-door treatment, about 58 per cent. recover of those who take advantage of the treatment in the early stages of the disease; and in many of the advanced cases the disease is arrested and life is considerably prolonged. Moreover, in large hospitals one-third of the autopsies held on persons who die of other diseases, show evidence of having had tuberculosis at some time from which they had recovered; showing that persons are frequently infected and recover therefrom, without their physician or themselves being aware of it.

When a physician has a patient whom he recognizes to be afflicted with pulmonary tuberculosis,

his first duty is to inform him that his sputum contains the germs of the disease, and that it is dangerous to himself, as well as to all others who come within his immediate environment; that he lives in the center of an infectious circle created by himself, but that by scrupulous care it lies in his power to dispose of his infectious secretions so as to render himself practically harmless; also that the efficiency of these preventive measures depends upon the promptness and thoroughness with which they are executed. Furthermore, that by observing strict precautions, he is not only doing his duty toward others, but he is also placing himself under the most favorable conditions for recovery. We have gained a very important point in the private prophylaxis of the consumptives when they realize the fact that their sputum is more dangerous to themselves than to others; that if they do not dispose of it in a proper manner they are liable to infect and reinfect themselves, thus virtually committing a slow suicide. It might seem of slight consequence whether a person whose lung already contains millions of tubercle bacilli inhales a few more or not. If we consider the nature of the local infective process in the lung tissue we are brought to the conclusion that self-infection plays an important rôle in the history of the disease, and doubtless often determines the fatal result. The pathological anatomy of a tuberculous lung shows that wherever there is a focus of infection, it is surrounded by quite an area of consolidation, the result of inflammatory exudation filling up the air cells and terminal bronchi. As a result of this diseased process, the power of inspiration is very much diminished in the portion of lung thus affected. In consequence of this impaired function, when germs are inhaled they will not find their way into the diseased area, but they will invariably be carried by the stronger air-currents into healthy portions of lung, and there form fresh foci of infection. We also know that when one lung is extensively involved, the capacity of the healthy lung is largely increased, thus compensating to a considerable degree for the disabled condition of the affected organ. In consequence of this enlarged capacity and function, the aspirating power of the lung is correspondingly increased, so that when air is breathed which contains bacilli, the chances are greatly in favor of their entrance into the healthy lung. I think in the majority of instances when only one lung is primarily involved the disease is transmitted to the other lung by the process of self-infection.

In commenting upon the personal prophylaxis of persons afflicted with pulmonary tuberculosis I cannot refrain from calling attention to the male invalid who is thus afflicted and permits the growth of a full beard. Some years ago I occupied a seat in a Pullman sleeper returning from a journey in the West. Directly opposite sat an individual whose appearance at first glance revealed the sad story that he was a victim of tuberculosis in its advanced stages, and probably was going home from some Western health resort. The appearance of his hands and the irregular outlines of his body indicated that he was nothing but skin and bones. His haggard countenance was hidden underneath a heavy growth of hair, which extended down to his waist. He coughed frequently, and his expectoration was free and quite copious. It is true he carried a spittoon, into which he attempted to deposit his sputum, but at every expectoration a portion of the secretion lodged in his beard and slowly trickled down its meshes. Every now and then he would wipe his beard with his handkerchief, thereby spreading the sputum more thoroughly, and placing it in a more favorable condition to dry. It was in the month of June, and the window near by him was raised, admitting the balmy morning breeze. The conditions were most favorable for the rapid drying of the sputum with which his beard was literally saturated. Had one had microscopic vision, I have no doubt but that thousands of tubercle bacilli could have been seen floating about in the atmosphere of that car. As I sat and contemplated this ambulatory magazine of putridity and pestilence, all manner of thoughts crowded themselves upon my mind, and various emotions took possession of me, some of which, I must confess, were by no means inspired by a spirit of Christian philanthropy. Here was a fellow who, according to the most conservative estimate, was producing seventy-two hundred millions of tubercle bacilli daily. Now if only one-twentieth of his sputum lodged in his beard he was endangering his surroundings with infection to the extent of twelve million germs. Had he been minus his hirsute appendage and had taken proper care of his sputum, his presence would have injured no one. The question was how many persons had this individual infected in his journey across the continent? And was there no authority by which his carnival of wholesale infection could be arrested. In those days I was an honored member of the Ohio State Board of Health and prided myself in being able to suggest a remedy for most any sort of a nuisance. The thought occurred to me, why not apply a lighted match to the reeking hot-bed of contagion, or in view of the fact that he had only a few days to dwell on earth, why not put an eternal quietus to that cough by severing his jugular? Had some person committed the latter act he would have doubtless been arrested and prosecuted for murder, but he would have been entitled to the gratitude of humanity for a life-saving service, and, well, it seemed to me that a very simple apology would have righted matters with the Almighty.

In our efforts to promote the prevention of tuberculosis we must always guard against the over-anxiety and terror which usually take possession of the laity in the presence of any form of contagion. Unreasonable fear is always due to ignorance or uncertainty. When the physician undertakes to enlighten his patrons on the subject he should not fail also to present the favorable and encouraging features which attach to it. The fact is that the precautions to prevent infection are more easily observed than those of any other of the infectious diseases. The entire prophylaxis is embraced in the simple postulate, *destroy all sputum before it dries.* The late researches into the natural history and biological peculiarities of the tubercle bacillus, have refuted many of the absurd ideas of malignant and direful attributes that were formally ascribed to it. The fact is, that it is a very feeble parasite as it succumbs very readily to natural influences outside of the animal body. If deposited on the earth the bacteria of decomposition destroy it with "neatness and dispatch." Kitosato has demonstrated that the majority of bacilli are found dead in the sputum at the time when it is expectorated, and that the most virulent forms no longer exist in dried sputum at the expiration of six months under the most favorable circumstances. Direct sunlight kills the bacillus almost instantly, and it perishes in a few hours if exposed to diffused light. Cornet found virulent forms in dust taken from a dark room near a bed in which a consumptive had died six weeks before. He seems to regard this as a rare example, so that the statement that a dwelling is saturated with the accumulated growth of years of the tubercle bacillus must be exceedingly overdrawn. So far bacteriologists have failed to find them in the dust on the

streets. That they are rapidly destroyed by antagonistic influences is evidenced by the fact that street sweepers, who breathe this dust continually, very rarely are afflicted with tuberculosis even though they follow their occupation for thirty years. An investigation of the history of coachmen has given the same result. If we remember that dust and soil contain millions of bacteria which speedily destroy tubercle bacilli and that they are also exposed to the destructive influence of sunlight and the atmosphere, it is not at all surprising that none have survived a sufficient length of time to be picked up by the most eager bacteriologist. It would seem, then, that we have the bacillus tuberculosis pretty well hemmed in, and that we are safe in concluding that it is not such an invincible ubiquitous monster as it has been represented. The fact is that is is found nowhere outside of the animal body in its virulent form, except in the immediate surroundings of persons afflicted with pulmonary tuberculosis who are careless with their sputum.

A few more rambling thoughts to serve as food for reflection and I have done. In a paper on microorganisms, read at Springfield, Ohio, in 1889, I advanced the theory of spontaneous pathogenesis, *i. e.* that the simple bacteria of decomposition under certain conditions and favorable environment, may become transformed into pathogenic or disease-producing organisms. For instance, in the case of typhoid fever—which is essentially a filth disease—the disease may arise from drinking water which is polluted by decomposing organic matter without the presence of the specific germ of typhoid fever, which are referable to an antecedent case; that the bacteria contained in the decomposing substance have acquired such pathogenic properties by reason of having met with the favorable conditions to effect this transmutation. Now it seems that the pedigree of the tubercle bacillus is not fully established either. Bacteriologists tell us of false tubercle bacilli which are found widely diffused in nature and resemble the true bacillus in so many respects that they cannot be distinguished therefrom without resorting to inoculation experiments. So far about thirty varieties of these bacilli have been discovered. Experimentally these false bacilli have been demonstrated to be pathogenic, but have not been found to be the causative agents of any special form of the disease. It affords me great pleasure to note that Klemperer, one of Europe's greatest pathologists, suggests the same theory as applied to the evolution of the tubercle bacillus that was advocated by myself with reference to the bacillus typhosus sixteen years ago. In speaking of the true and false tubercle bacilli he says: "Their difference in virulence and morphology are not fundamental, but have resulted through adaptation to various environments;" and he believes that the bacillus tuberculosis may be considered an acid-proof saprophyte that has subsequently become a parasite.

A deliberate consideration of the foregoing conclusion leads us to the inquiry whether future scientific research will not reveal other sources of infection than the sputum of the consumptive individual. The developments of late years have placed infection preëminently in front as the cause of tuberculosis and left heredity resting upon a very flimsy foundation. Hereditary predisposition is admitted as a secondary factor and yet the term is sort of a mysticism, which does not fully conform with the apparent facts as they appear to us from our professional observation and experience.

A comprehensive view of the tuberculosis question discloses a haziness upon the horizon of the scientific field, which suggests that there may be an unexplored region beyond, which the most profound scientists have not yet approached.

A CASE OF HODGKIN'S DISEASE WITH BUT SLIGHT ENLARGEMENT OF THE SUPERFICIAL LYMPH GLANDS.

By HENRY FARNUM STOLL,

HARTFORD, CONN.

Nellie B., aged 35, unmarried and a domestic, was admitted to the medical service of Dr. W. W. Knight at the Hartford Hospital, August 19, 1904, the writer being house physician at the time. The case is reported through the courtesy of Dr. Knight. Family history, negative. Personal history: Had measles and typhoid when a child. Has always been well until present illness, which began five years ago. At that time she observed that the glands along the right sternomastoid muscle were enlarged. Shortly after a "bunch" apepared above the right clavicle and about one year ago the left supraclavicular glands became enlarged. Their increase has been gradual and marked by periods of diminution in size. Synchronously with the glandular enlargement the patient began to tire more easily. The asthenia steadily increased and was associated with a great deal of gastric disturbance. Two years ago an attack of gastritis was accompanied by a severe diarrhea which lasted eight weeks and at this time some swelling of the feet was observed. Fourteen months ago she became acutely ill, being delirious and having a high fever, and a cutaneous eruption, which consisted of "red blotches," that appeared first on the neck and extended over the body. It was neither scaly nor puritic, and lasted about nine days. The duration of the attack was two weeks. She has had amenorrhea for two years. As she was complaining of a cough and night sweats the diagnosis of tuberculosis was made and the patient entered the Tuberculosis Annex of the Hartford Hospital, where she remained less than one week. Examination of the lungs showed slight dullness and a few crepitant râles below the right clavicle following coughing. No tubercle bacilli were found in the sputum. For the next three months the patient had a fever of about 102°, and the abdomen was distended and tender. In May, 1904, she went to Saranac and remained there three months. During that time she was under the care of Dr. E. R. Baldwin, to whom I am greatly indebted for very complete data concerning her case while there. There were no signs of tuberculous lung involvement, and tubercle bacilli were not found. A marked diazo reaction was present twice, but three Widals were negative, as were a blood culture and a tuberculosis agglutination test. During July the spleen was observed to be enlarged and the abdomen was slightly distended and tender. For a number of days the patient seemed very ill. Her gums were swollen and bled easily (a similar condition was noted in Pilcher's case). No diagnosis was made at Saranac. She came directly to the Hartford Hospital from there, and her condition was as follows: Patient walked in hospital; well developed but considerably emaciated. Skin and mucous membranes are pale and there is a sallow tinge to the former. The tongue is moist and clear; teeth in poor condition. The tonsils are normal. The supraclavicular glands of both sides are enlarged, those of the right side being larger. The chain posterior to the right sternomastoid muscle is enlarged slightly. The skin is not discolored over the glands which are freely movable, not tender and not matted together. The largest, which is above the right clavicle, is about the size of an English walnut. Neither the axillary, epitrochlear nor inguinal glands are en-

larged, but on deep palpation an enlarged chain can be felt just above the left Poupart's ligament.

Lungs.—Slightly impaired, resonance below right clavicle and a few subcrepitant râles over left lower lobe posteriorly. Otherwise negative.

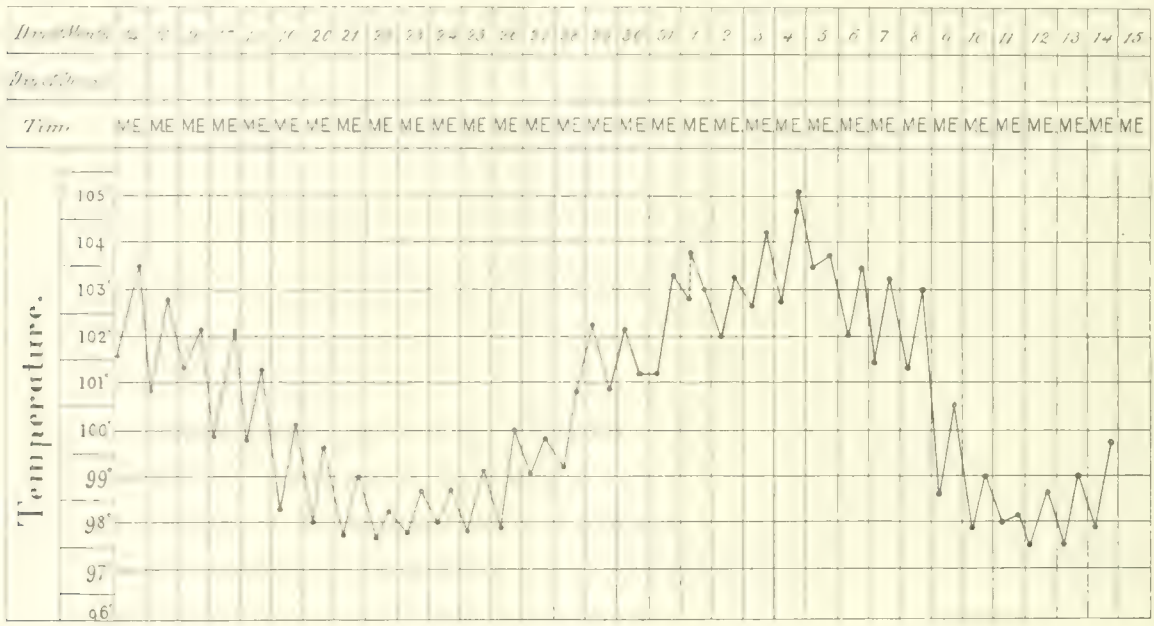
Heart.—Action regular, not enlarged. A systolic murmur follows the first sound at the pulmonic area and also internal to the apex; it is not transmitted. The second sounds are not accentuated. Arteries are not thickened. There is a slight brownish discoloration of the skin over the right upper quadrant of the abdomen. There is no tenderness and the abdomen is flaccid.

Liver.—Relative dullness in fourth space, lower border, two inches below costal margin. It is not tender.

Spleen.—Increased area of dullness and lower border is two inches below the costal margin and slightly tender. Rectal examination, negative. The urine was normal except for a slight increase of indican. Clinical diagnosis. Hodgkin's disease. Fowler's Solution was begun at once, but was changed to sodium cocodylate gr. ¾ daily, given hypodermically for one week, during which time the hemoglobin dropped from 43 per cent. to 37 per cent. and the red cells from 2,200,000 to 1,700,000. The latter part of August *x*-ray treatment was begun; the glands above the clavicles and above Poupart's ligament were exposed for ten minutes at a distance of three inches at first daily, later on alternate days and when the treatment was discontinued, at the end of six weeks, the glands were scarcely perceptible. In addition to the regular diet she had extra eggs and milk and was in bed on the veranda constantly for five weeks.

Coughing spells were severe at times, the expectoration being mucoid and not containing tubercle bacilli. Profuse night sweats were relieved by atropine and camphoric acid. She was discharged October 10, slightly improved. I saw the patient with Dr. O. C. Smith the last week in October at her home. Emaciation was extreme, the respirations were hurried and shallow and the end seemed not far off. Subcrepitant râles were heard over the lungs posteriorly, and at the apex of the right lower lobe, the respiratory murmur was very harsh and the voice conduction increased. The abdomen was moderately distended, appeared to contain a small amount of fluid, and was uniformly tender. The abdominal picture was suggestive of a peritonitis. The supraclavicular glands were not visible. She failed steadily, dying October 31. A similar termination was present in one of Einhorn's cases who "suddenly took ill with symptoms of a peritonitis and died in four days."

It was impossible to obtain a complete autopsy, but permission was procured to remove the glands above the right clavicle. Dr. Walter R. Steiner, the attending pathologist to the Hartford Hospital, very kindly examined them, and his report is as follows: "The section shows a marked thickening of the gland reticulum as well as an extensive formation of coarse bands of connective tissue which anastomose with one other. There is also to be seen some proliferation of the endothelial cells, and giant cells of the uninuclear and multinuclear type. There is a considerable number of eosinophiles present. Diagnosis. Hodgkin's disease. In considering this case the following points seem of especial interest: (1) The development of acute symptoms associated with an eruption nearly four years after the beginning of the disease. (2) The slight involvement of the superficial glands. (3) The occurrence of peri-



odical abdominal distension and tenderness. (4) The alternating periods of pyrexia and apyrexia. (5) The unusually severe anemia. (6) The disappearance of the glands before death.

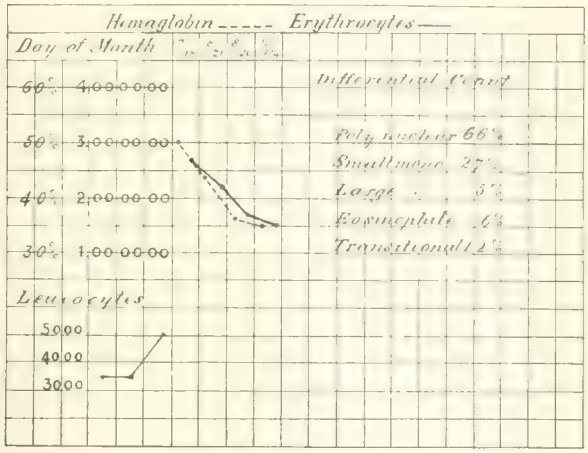
"It seems almost conclusively shown that lymphadenoma is an infectious disease, occurring in both an acute and chronic form, but that the organism or organisms which are the true cause of the disease have still to be discovered" (Clark). We are as much in the dark to-day concerning the etiology of this fatal malady, as was Hodgkin when he described the disease in 1832. By observing the occasional evidences of tuberculosis in patients presenting the clinical picture of Hodgkin's disease, Sternberg was led to the conclusion that lymphadenoma was a lymphatic tuberculosis, and his views were rather generally accepted as the true explanation of a vexing question. But it remained for Reed of Baltimore to prove conclusively that, though the two conditions might be present in the same gland, yet they were distinct and absolute entities. Her observations were confirmed by Longcope, Simmons and others.

From time to time cases have been reported where the infection appeared to have taken place through the mouth; for example two of Wood's cases. One had an alveolar abscess near the right lower molar

tooth and the lymph glands at the angle of the jaw on that side became enlarged. This proving to be the beginning of a general lymphadenoma. The other case was identical save that the condition started in a severely inflamed tonsil. The mode of infection by way of the mouth is also suggested by the fact that the lymph glands which receive the lymphatics from the mouth and pharynx are usually the first to be involved.

At other times scarlatina, measles, pertussis, variola or some other acute disease directly antedates lymphadenoma, and one wonders if they are etiologically related. Even more difficult of explanation are those infrequent cases which appear to be caused by trauma. Thus, a patient of Jones' was kicked in the perineum and very shortly a gland posterior to the anus became enlarged. This was followed by the enlargement of all the glands about the rectum, and subsequently the superficial lymph glands were involved. The course was an acute one, the patient dying in five weeks.

Though the etiology of the disease remains obscure, its pathology has been very carefully studied. In the early stages there is considerable increase in the endothelial cells, eosinophiles are abundant, and numerous uninuclear and multinuclear giant cells



are observed. Later, fibrous tissue, which is not extensive in the early specimens, is very abundant, replacing, as it does, all the glandular element. Nodules may be present in the viscera which have the same microscopical appearance as the lymphatic glands.

The blood shows a secondary anemia not usually as severe as in the case here considered. The leucocytes are inconstant. They may be increased, diminished or normal, nor is the differential count distinctive.

Symptoms.—The onset in the great majority of the cases is insidious. The glands enlarge slowly and painlessly and show considerable variability in size at different periods. Some time may intervene between the glandular enlargement and the occurrence of subjective symptoms, though usually they occur synchronously. A loss of flesh and strength are commonly the first things complained of. Frequently an annoying cough is present during the early days and is caused by pressure on the recurrent laryngeal nerve. As the anemia becomes more marked the patient suffers from dyspnea on exertion and possibly edema of the legs. Some gastric disturbance is usually present: often a diarrhea occurs. Some fever is noted in nearly all cases; it may be continuous, intermittent or remittent. In 1887 Ebstein described a "Chronic Recurrent Fever, a New Infectious Disease." Similar cases subsequently proved that these were examples of Hodgkin's disease, in which the febrile and afebrile periods alternate with surprising regularity. Ebstein was not the first, however, to observe this phenomena, for in 1875 Southey mentioned it as occurring in some of his cases. The pulse follows the temperature and the respirations are slightly accelerated. In women we often get some changes in the menstrual history, amenorrhea being the most common. Hemic murmurs are usually heard over the heart. Pressure symptoms are diverse. They commonly occur late in the disease, though they may be present early. Edema of the face and of the legs are the result of obstructed venous return, while dyspnea or dysphagia occur as the trachea or esophagus is pressed upon. Where the mediastinal glands are large and press on the bronchi, manubrial dullness may be elicited and some modification of the respiratory murmur, and râles will be heard over the corresponding part of the lung. A cough may be the result of pressure on the recurrent laryngeal nerves. Abdominal tenderness and ascities are due to the involvement of the mesenteric and retroperitoneal glands and especially to those at the lilus of the liver.

Cases of this class run a slow course with periods of seeming improvement and terminate fatally in from two to five years as a rule. At any time they may suddenly develop acute symptoms, as did the writer's case. Very different are those cases, fewer in number, which begin acutely with diarrhea, vomiting, abdominal pain, fever and occasionally with delirium. In a number of cases an eruption of protean type has been associated with the period of invasion. Again, other cases begin with pains in the legs and arms.

With limited facilities for reference I was unable to refer to more than one hundred cases, and in only about eighty were the clinical histories complete. A large majority of the cases beginning with a definite invasion had gastrointestinal symptoms.

Thus, in twelve cases mention was made of some or all of the following, viz., headache, malaise, nausea and vomiting, diarrhea and abdominal pain, usually of a colicky type. Pruritus of the skin, most commonly over the tumors, may be present, with or without an eruption. The rash is inconstant in type and was mentioned as occurring in eight cases, being erythematous in four cases; eczematous in one; psoriatic in one; "a macular eruption" (?) in one; and papular and erythematous in one.

Broadbent attributed the skin lesion and pruritus in his case to the arsenic the patient had been taking. While that may have been true, one can hardly assume that all the cases which began acutely and were associated with a rash had been taking arsenic prior to their illness. Dr. Shoemaker kindly wrote me that his case had no arsenic either before or during the time he was under his care. His belief that the eruption was really a part of the disease seems a correct one. In some cases a purpuric condition of the skin is present. Bronzing of the skin, which was present in our case, to a slight extent, is observed at times. A number of cases had convulsions toward the end of the disease.

Diagnosis.—No difficulty is experienced in making a diagnosis of lymphadenoma when the patient presents himself with huge bunches in his neck, axilla, and groin. But in those cases where the involvement of the superficial glands is slight, the condition is often thought to be a tubercular adenitis. Yet, the tendency of the glands in the latter disease to become matted together, thus loosening their individuality, and their proneness to caseation and suppuration, will, as a rule, serve to distinguish them. Both conditions may occur in children, but a tuber-

cular adenitis is by far the more common at that time, while the reverse is true in adults.

The first glands to be involved in a tuberculous process are those at the angle of the jaw as a rule, while in Hodgkin's disease the glandular enlargement is commonly first observed in the chain lying along the sternomastoid muscle.

When the mediastinal glands press on the bronchi to a considerable degree, the diagnosis of pulmonary tuberculosis is not infrequently made. This is especially true if the superficial glands are only slightly or not at all enlarged, and it may be that the diagnosis can be arrived at only after the case has been observed for a considerable time, for the clinical history of the case may be very suggestive of tuberculosis, as also the signs in the lungs. If the involvement be chiefly of the abdominal glands, the condition may simulate tuberculous peritonitis, tabes mesenterica, or typhoid fever.

As it is of prognostic as well as therapeutic importance that the condition be diagnosed, a gland should be removed and examined microscopically, and when possible an inoculation test made. When still in doubt, tuberculin or the tuberculous agglutination test may serve to exclude tuberculosis. Yet the interpretation of the result may be erroneous unless one understands that both conditions may be present.

An absence of the rose spots, a continuously negative Widal, and the repeated failure to isolate typhoid bacilli from the blood, would differentiate the condition from enteric fever. The alternating periods of pyrexia and apyrexia are quite distinctive of Hodgkin's disease.

Prognosis.—Most cases are fatal in from four months to as many years. Just now great hopes are entertained by a number of well-known men that the *x*-ray will prove of real value, and the cases reported by Parsey, Williams, Childs, Cooler, and others are certainly encouraging. Yet no more so than some of the results obtained with arsenic; for instance, the case reported by Blakewell of a man with extensive glandular enlargement and very urgent dyspnea was apparently cured by the use of Fowler's solution. On the other hand, the cases of F. H. Williams and Shoemaker were not improved permanently by the *x*-ray. Cases are not wanting that have been cured by poultices, and even mud, locally.

It should not be lost sight of that the glands fluctuate considerably in size, and even may disappear before death. It is but natural that these periods of improvement should be attributed to the particular medication that the patient is receiving at the time. Thus Ely found that an ointment containing menthol and salicylic acid, and an alterative mixture of the chlorides caused the glands to disappear and the skin lesion to clear up. A study of the accompanying blood chart is of interest when one considers that the reduction in size of the glands went hand in hand with a steadily increasing anemia! And after all, the glandular enlargement is not Hodgkin's disease *per se*, but only one manifestation of a grave constitutional condition.

The disappearance of the glands before death, suggests those cases of diabetes in which sugar is absent in the urine before an attack of coma, and the rarer cases of gout where the joint pains subside before the onset of the so-called suppressed or retrocedent gout.

Treatment.—One must endeavor to improve the state of the general nutrition in every possible way, and the rest cure, with an abundance of fresh air and food, is the best means of achieving this end. Arsenic, either Fowler's solution, or the sodium salt of cacodylic acid should be given in relatively large doses. The glands should be exposed to the *x*-rays for a long period, and the earlier such treatment is begun the better will be the results. Removal of the glands is to be resorted to only when pressure symptoms are marked, as they recur. When one sees a case steadily advance to a fatal termination, in spite of the employment of what is considered to be the best therapeutic agents, he feels as Trousseau did, when he said concerning the treatment of this malady, that it was "beyond his practice."

VENTRAL DECUBITUS AS AN AID TO DRAINAGE FOR DIFFUSE PURULENT PERITONITIS.

By R. M. HARBIN, M.D.,
Rome, Ga.

There are as yet no ideal methods for draining the peritoneal cavity because of obvious mechanical difficulties, and as the value of utilizing postural gravity methods as an aid has not been realized as fully as the merits of the procedure would warrant, a case in point will be briefly narrated.

J. B., a wholesale merchant, 44 years old, had his first attack of appendicitis December 29, 1903, which was attended with violent pains, vomiting, chills, and high temperature lasting three days, all of which rapidly subsided in a few more days. He had been more or less dyspeptic and constipated for a number of years. His second attack occurred just one year later, with the same symptoms, and after twenty-four hours he experienced very acute pain in the right iliac region with a progressive rise of temperature and pulse rate, marked rigidity of the abdominal muscles and vomiting. His pulse rate was now 110 and temperature 102° F. At the end of forty-eight hours from the beginning of the attack, the abdomen was opened by a four-inch incision about three inches above and parallel to Pouport's ligament. About an ounce of seropurulent fluid appeared at the opening, and was carefully mopped away, and then the deeper parts were similarly dealt with. Three drains of washed iodoform gauze, four layers thick and four inches wide, were inserted, one deeply into the iliac fossa well under the caput coli, one down to the pelvis, and one to the left. No search was made for the appendix, as there were signs of shock, and after the patient recovered from the ether, morphine and strychnine were administered. In three hours he had reacted well and was quite comfortable. He was now brought near the edge of the bed on the right side with the left arm hanging out and the right one drawn from under the chest. He could remain in this position comfortably for half an hour, and then was allowed to resume a latero-prone position, and occasionally

rested by being shifted back to the dorsal position. During the first six hours the drainage was very large in amount, saturating the dressings and sheets with a pinkish serous discharge. Towards the end of the first twenty-four hours the outer dressing of the wound was changed. The pulse now was 90, temperature 100° F., and the bowels moved spontaneously. For the next twenty-four hours the amount of discharge was probably 50 per cent. less and then the drains were removed and a deep one replaced in the right iliac fossa, the others being superficial. The discharge grew gradually less, and in a week had practically ceased. It required four weeks for the superficial wound to heal. The left lateral position was not allowed for three weeks. Retention of urine required the use of a catheter, which finally produced a cystitis which made a troublesome but not a serious complication.

The amount of discharge in this case by far exceeded what I have ever seen from any other abdominal wound, and the amount of toxic material in the peritoneal cavity thus eliminated readily explained the rapid improvement of his symptoms and final recovery. The peritoneum furnishes a broader area for absorption than other serous surface in the human organism, and for this reason generalized infections are attended by high mortalities. Of course much depends on the type of infection, some bacteria being more virulent than others. In a normal condition of the peritoneum the adjustment of inflow and outflow is such as to keep the serous membrane constantly moist. Experiments have proved that the peritoneum is capable of great powers of absorption, and in a dog or rabbit a collection of fluid equal to 10 per cent. of the body weight can be absorbed in thirty minutes (Kelly). In peritoneal infections bacteria and their toxins are thus taken up and distributed through the thoracic duct to the general circulation. So the great desideratum in drainage of peritoneal infections is not merely to give exit to the exudative products but also to establish a reverse irrigation current of serum from the blood, thus washing away the toxins, and this is facilitated by the mechanical presence of gauze, together with the effects of gravity.

Irrigating the peritoneum with normal saline solutions only dilutes the toxic products, and it is left for the various emunctories to eliminate or destroy such poisons.

The tendency of nature is to circumscribe various foci of infection which might be drained rapidly by gravity methods. In the ventral position it is easy to understand that the intestines with their gaseous contents would occupy the highest position in the abdominal cavity, and the fluid exudates make their way to the abdominal parietes. Of course it is not expected that a patient could maintain this position constantly, but an occasional resort to it is sufficient to keep open the channels towards the abdominal wound before pocketing of the discharge takes place.

SANITATION OF THE SUMMER CAMP.

By HARVEY B. BASHORE, M.D.,
WEST FAIRVIEW, PA.

Camp-life is beginning to be so great a factor in American life that it deserves a little attention from sanitarians, inasmuch as one frequently hears of sickness being attributed to this source. Just as I am writing this I notice a report of an increased amount of typhoid fever in all sections of New York State, and the health authorities investigating it have found that the sufferers in a great part are those who have passed their summer holiday in the country. With reports like this frequently appearing, there can be no question but that camp-life, in many cases, has been and is a source of danger, if one neglects or is careless in regard to the usual sanitary rules. We are apt to think that everything in the woods is so fresh from the hand of the Maker that sanitary care is unnecessary; every spring and every brook seems to be pure and undefiled. If we could only drop into the "forest primeval" such indeed would be the case, but the fact is that, wherever you go, someone else has been there before. I recall an illustration of this somewhat to the point which occurred to a friend of mine who was tramping through the wilds of Canada north of Lake Ontario. One day, coming across a grave, he remarked to the guide that he didn't suppose people died here. "Yes, they do, and of typhoid fever and diphtheria," was the answer.

Let us investigate, first, the permanent camp, which is occupied summer after summer. This, like any other habitation, evidently needs some care to keep clean. It will not be sufficient to throw waste materials just outside the door, for this is not only unsightly, but tends gradually to cause pollution of

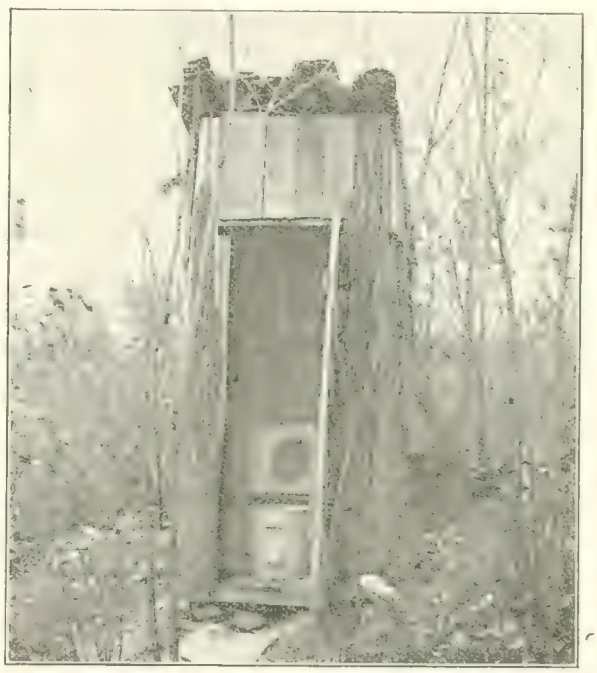

Fig. 1.—The sanitary arrangements for a permanent camp.

the soil, air, and water, just the very things one expects to avoid in taking to the country. Tin cans, waste paper and offal littering the virgin soil around a beautiful camp are even more jarring to one's sensibilities than when scattered about the village alley. There is, fortunately, no complicated system of waste disposal in the camp, as in the city. All combustible rubbish should be burned, and the non-combustible, of which there will not likely be much, should be buried. All putrescible waste—that is, garbage—should be put into a regular garbage hole and covered every evening at least with earth. This hole can be in some unfrequented place or behind some cluster of bushes or trees, so as not to detract from the beauty of the place nor offend one's senses.

The only other waste to dispose of is human excreta, and this is by far the important one, for man's waste products are poisons when again taken into the system. The best way and the only proper way to dispose of this is by some form of dry closet; it need not, however, be elaborate in order to be effective. The one shown in the cut is made of rough slabs and in the crudest manner, yet it is perfect in its sanitary appointments, vastly better than many a

city water closet. I have frequently had friends inspect this, and they invariably remarked that the distinguishing odor was that of the cedar shingles used in constructing it. The earth used in the pail is taken directly from the field a few yards away, and the contents of the pail are emptied on the same field only a short distance from the camp, yet after this is covered with a little earth one can pass the spot without knowing it.

In regard to the water supply of a camp, it is hardly necessary to call attention to the fact that it is not safe to drink from every brook or spring one comes to. A good rule is always to see the other end first, or at least have knowledge of its entire drainage basin, whether spring or brook. Everything else being equal, springs and brooks having no human dwellings on their drainage areas are practically safe. When I say dwellings, I mean also temporary camps, for they are at times even worse than permanent dwellings as a focus of infection.

The temporary camp of a week or so, it is needless to state, hardly requires the same sanitary precautions as a permanent camp, yet a hole for garbage is a very desirable thing, and may save trouble for those who come after. A dry closet such as described for a permanent camp is not to be thought of, but a very good substitute is a sink similar to that used by soldiers in the field; simply a short trench in the ground and a support as shown in the photograph. Such an arrangement hidden by a clump of bushes, covered frequently with earth, and not placed near a water course is perfectly satisfactory from a sanitary point of view. If even this is too much trouble, there yet remains the "method of Moses," which has stood the test of some 3,000 years, and can still be recommended. "And thou shalt have a paddle upon thy weapon; and it shall be, when thou wilt ease thyself abroad, thou shalt dig therewith, and shalt turn back and cover that which cometh from thee" (Deut. xxiii. 13).

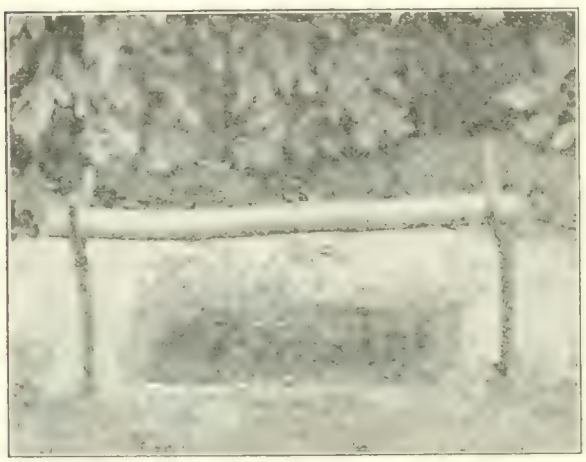

Fig. 2.—The sanitary arrangements for a temporary camp.

For the water supply of a temporary camp all the rules hold good that were mentioned in regard to the water supply of a permanent camp. There is one additional point, however, that is worth mentioning: if the circumstance should arise when one must use the water from some suspicious stream, it is well to practice the plan used by the natives of India, who dig little holes in the sand of the shore until they get below the water level; these holes soon fill with clear water, which, having filtered through the surrounding sand, is vastly safer than the raw water of the stream.

Filariasis in Man Cured by Removal of the Adult Worms in an Operation for Lymph Scrotum.—A. Primrose states that filariasis is very rarely met with in Canada. The patient whose history he here reports had lived in Barbados all his life, with the exception of a few short trips which he had made to Canada and Europe. When he was twenty-eight years of age he suffered from what was thought to be hydrocele. Both sides of the scrotum were tapped and fluid drawn off, after which iodine was injected. This seemed to effect a cure. Three years later on one occasion he had a sudden attack of illness. There was an initial chill, followed by high fever and drowsiness. A painful swelling of the right leg below the knee developed. From this attack, too, he fully recovered. Two years later a similar attack occurred, while in addition the glands in the right groin became swollen and tender. These attacks occurred from time to time for the next few years. During one of them an abscess developed in the calf of the right leg. After being opened it healed without much trouble. At this time the scrotum first began to be affected. The swelling of this organ became a feature of all subsequent seizures. Soon permanent thickening resulted. The patient never suffered an attack while in a cold climate. Although filariasis had never been suspected in this case until he came under the author's care, his history would indicate that he had been a victim of the infection for possibly twenty years. When examined by the author, the scrotum was seen to be a somewhat flabby mass, about three times its normal size. Its tissues had a thick, indurated, leathery feel on manipulation, and there was some additional enlargement in the region of each testicle. On the right side there was a nodule about the size of an almond, apparently in the epididymis. On the writer's first examination of the patient he suspected that he had to deal with a case of lymph scrotum, probably of filarial origin. Later examination of the blood taken from the finger tip showed the embryo filaria in large numbers. The parent worm was isolated from the tissues which were excised at the operation. Forty-six days after the operation the patient suffered from an attack of lymphadenitis in the neck, with the characteristic symptoms of the elephantoid fever. This was the only attack of this fever which the patient had in a cold climate. It might be accounted for by supposing that immature ova had been discharged into the circulation by the parent worms during manipulations at the time of the operation. In less than a month after this attack of fever no embryos could be found in the blood, and none was discovered on later occasions, although many attempts were made to secure a specimen. It is therefore seen that the patient was not only freed of his lymph scrotum, but that the operation had resulted in freeing him of his filaria. This is probably due to the fact that the filaria found in the excised tissue were the parent worms, which were responsible for the production of the embryos in the blood, and that on their removal the embryos were no longer produced, while those already in existence gradually disappeared, since they never come to maturity in the human blood, and must perish unless they are carried to an intermediate host.—*The Canadian Practitioner and Review.*

A Simplification of the Thiersch Method of Skin Grafting.—Isnardi says that for the past eight years he has been making his Thiersch grafts without disturbing the granulations on the surface to be covered. Asepsis of the regions to be operated on is imperative and the granulations must be small, firm, pink, and healthy. When the grafts are in place they are covered with loose meshed gauze and a wet dressing of 3.5 per cent. boracic acid. The dressing is changed every twenty-four hours, or if there is suppuration, every twelve hours. On the eighth day the gauze in contact with the wound is changed for the first time, a dusting powder and lanoline are applied, and the whole is covered with dry cotton and gauze. The author has obtained constantly satisfactory results by this method, and commends it as simpler and more certain than the plan of curetting the granulation before transplanting the grafts.—*Zentralblatt f. Chirurgie.*

MEDICAL RECORD.

A Weekly Journal of Medicine and Surgery.

THOMAS L. STEDMAN, A. M., M D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 FIFTH AVENUE.

New York, May 20, 1905.

A NEW TEST OF GASTRIC EFFICIENCY.

THE theoretical and practical objections to the ordinary method of testing the efficiency of the gastric functions by means of the analysis of the products of digestion obtained through the stomach tube a certain length of time after the ingestion of a test meal, have led to much dissatisfaction with the procedure. In timid patients the secretion of gastric juice is always modified more or less profoundly by inhibitory reflexes dependent on dread of the approaching ordeal of lavage, the test meal is not of a nature to stimulate the gastric activities to the greatest degree, the time of extraction is a purely arbitrary one, and the passage of esophageal instruments is extremely undesirable in some cases, and out of the question in others. Among others, Sahli of Bern, has devoted much attention to the subject of gastric analysis, and the butyrometric method devised by him and applied to a test soup composed of butter, flour, and water, was a distinct advance in the direction of accuracy.

In a recent contribution (*Correspondenz-Blatt für Schweizer Aerzte,* April 15 and May 1, 1905) this observer describes the steps by which he was led to develop a procedure which he considers renders it possible to study the actual efficiency of the stomach's digestive powers, uninfluenced by disturbing outside influences, with a greater degree of accuracy than has heretofore been possible. The principle involved is somewhat similar to that made use of in the same author's method of estimating intestinal digestion by administering an agent like iodoform which is readily recognizable in the urine, in capsules composed of material readily soluble in the pancreatic ferments, but impermeable to the gastric juice. Such capsules may be prepared of glutoid, a resistant material obtained by treating gelatin with formaldehyde, but the problem of securing a material which should be easily digestible in the stomach but able to withstand the intestinal juices and also putrefaction, was very difficult. Connective tissue which has not been subjected to the action of heat is, however, such a substance, and Sahli's first experiments were made with goldbeater's skin. This is prepared without the intervention of heat from the cecum of the ox, and theoretically should serve well for the desired purpose; but owing to the lack of uniformity in the commercial product, comparative tests would not be feasible, and further search was necessary. The method finally adopted consists in the use of a pill containing a small amount of either iodoform or methylene blue, which is enveloped in a small bit of the rubber dam used by dentists, the neck of the little bag formed being tied off with the finest obtainable raw catgut. Such a pill is given at the end of the ordinary noon meal and the urine passed at stated intervals during the afternoon and evening is either examined in regard to the first appearance of a greenish color if methylene blue was used, or is tested for the presence of iodoform in case this indicator was chosen. The latter substance has the practical advantage that it may be detected with equal certainty in the saliva. The appearance of either substance in the urine, or of iodoform in the saliva, indicates satisfactory gastric digestion and a negative result the reverse, the information obtained being, according to the author, a sufficient index as to the combined activity of the hydrochloric acid and the pepsin.

This test does not merely indicate the length of time required by the stomach for the digestion of raw catgut, but it affords a reliable criterion of the degree of digestion undergone, under absolutely undisturbed conditions, by the meal of which the pill formed the conclusion. Extensive observations have led the distinguished Bernese clinician to ascribe the greatest value to this "desmoid reaction," as he terms it, and he believes that it will serve in many respects to clarify our conceptions of the physiology and pathology of the gastric functions.

UNCINARIASIS IN PORTO RICO.

SINCE our occupation of Porto Rico and the Philippines, tropical diseases have assumed an importance to American medical men, always well deserved, but hitherto unrecognized. For our information on tropical diseases we have been dependent upon two or three most admirable text-books (such as Manson's and Scheube's), which cover the whole subject; while for special districts or diseases we have, in the past, often had thrust upon us the observations of travelers and visitors, more or less qualified, and the parboiled effusions of self-constituted or irresponsible "investigators" only too eager to drop their "new discoveries" into the voracious maw of the lay press. Such writers generally know nothing of the habits and condition of the people they visit, and upon whom they inflict their observations, and are equally ignorant of what scientific investigators have already accomplished in the field which they assume to have been virgin. In refreshing contrast to one of these reports of a "special commissioner" of a New York newspaper, is the previously published governmental "Report of the Commission for the Study and Treatment of Anemia in Porto Rico."

The disease is caused by the presence in the intestine of a parasitic worm, *Uncinaria americana.* The symptoms are similar to those caused by *Uncinaria duodenalis,* but the two parasites are in some respects quite dissimilar, the chief differences between them being (1) in the nature of the buccal armature, and (2) in the size of the ova. The parasites are seen in the feces as little threads of a white, gray, yellow, or blood-red color, and are about 1 cm. in length. The ways in which infection may take place are through the ingestion of the larvæ and through penetration of the skin by the larvæ and their subsequent migration to the small intestine. The report discusses these points in considerable detail, as also the diagnosis, symptomatology, pathology, course, and prognosis of the resultant disease. Prophylaxis and treatment are, naturally, among the most important and practical points on which

information is required; and here the authors of the report (Drs. Bailey K. Ashford, W. W. King, and Pedro Gutierrez Igaravidez) are most satisfactory and precise in their statements. Pollution of the soil having an important significance in the transmission of the disease, prevention of this is naturally a main factor in the prophylaxis. But this is a difficult task. It takes a long time to teach people, living as the poorer and laboring classes in the tropics do, to change the habits not only of a life-time, but also of a traditional and practically limitless past. The use of properly constructed latrines and the wearing of shoes will doubtless do very much towards eliminating this disease; but whether these two luxuries will ever be regarded as necessities by the Porto Rican peasant, we may consider an open question. However, an attempt is being made to inculcate these civilized ideas, and it is only along such lines that success will be obtained in the effort to eradicate uncinariasis. The only drugs found to be of real value, are thymol, male fern, and beta-naphthol.

As an indication of the amount of work accomplished by the commission, it is stated that as many as 500 or 600 patients a day were examined and treated. "Of 5,500 cases of anemia, 5,490 of which were due to uncinariasis, we lost 27 patients. Thirteen of these died of uncinariasis pure and simple, and of them five never received an anthelmintic. Nine died of other diseases or of complications, with uncinariasis as a more or less potent contributing factor. Two of these died of direct sequelæ of uncinariasis. Five died of diseases in which uncinariasis was not, even remotely, a contributing cause. Thus our total mortality from all diseases was .49 per cent. Our mortality for uncinariasis alone was .23 per cent., and including all those who died from uncinariasis alone or as a concurrent cause .41 per cent."

The report is published both in English and Spanish, and is a document of great value, as the disease in question is prevalent in other of the West Indian Islands, and when epidemic, as was recently the case in Porto Rico, is accompanied by a high rate of mortality. The authors say with truth that "Porto Rico has taken the initiative in the tropics in inquiring into the cause of the profound anemia of her laboring classes, and in testing feasible means of treatment and prophylaxis"; and, we may add, with equal truth, that the isolation and possible eradication of the so-called Porto Rican anemia will prove to be among the best results of the American occupation of that island; and the credit for such will be due, in very large measure, to the labors of the authors of this interesting report.

Injurious Effects of Athletic Games Upon the Body.

In view of the fact that athletics play so prominent a part in the curriculum of all our large universities and colleges, it would be both useful and instructive to ascertain the effect upon the body of such exertions. It cannot be denied that in American universities athletics of all kinds, and especially football, are carried to excess. Much valuable time is wasted and decided harm in many instances is done to mind and body by a too strenuous participation in games. The practice of athletics in discretion is beneficial, but when regarded as the chief end and aim of college existence it is harmful in the extreme.

Colonel Valery Havard discusses the matter at length in the March issue of the *Journal of the Association of Military Surgeons* and amongst other conclusions says that not only is the circulatory system damaged in excessive and long-continued athletic training, but other organs may likewise suffer. He considers the question as to whether the active athlete may render himself susceptible to phthisis by undue exertions and concludes that the point is undecided. The liver of the athlete who does not adjust his diet to his quieter after-life is likely to become congested, torpid, and sluggish; and such a condition is generally accompanied by digestive disturbances. One of the most frequent evil effects of violent athletics is renal congestion and overstrain, and severe and protracted muscular effort may lead to interstitial nephritis.

Sanitary Conditions in Canadian Factories, Workshops, and Barber-Shops.

In the Sanitary Journal of the Provincial Board of Health of Ontario, Vol. 22, Parts 3 and 4, Dr. Thomas Keilty, Provincial Factory Inspector writes on the above subject. The manner in which factories and workshops are kept is a most important factor in the preservation of the health of the general public. In no one way, with the possible exception of schools, can disease be more easily spread than by means of unsanitary factories and workshops. It is, therefore, an essential object in the interests of public health to insist that all precautions should be taken to prevent the spread of disease among communities of workmen. Dr. Keilty states that at the last session of the Ontario Legislature amendments to the Factories Act were passed providing for more sanitary conditions in supplying drinking water, the heating of workshops, providing closet seats for a given number of employees, the standard being at least one seat for each twenty-five employees, and providing for spittoons on the recommendation of the Factories Inspectors. Referring to barber-shops which are in an unsatisfactory state from a hygienic point of view, the writer thinks that a movement to better the existing state of affairs should be initiated and recommends the following conditions adopted by a barber in Woodstock, as worthy of example. All towels before being used are laundried. All tools used are disinfected by formaldehyde gas. All razors immediately after being stropped are dipped into a solution of bichloride of mercury. Each customer is supplied with a brush thoroughly cleansed in a solution of bichloride of mercury. No shaving cups are used, the cream is made from shaving soap, which is pressed from a tube.

A Panama Canal Suggestion.

Lindon W. Bates has just issued a publication with this title, in which he adversely criticises the plans formulated for the construction of the Isthmian Canal, and in which he suggests alternative methods. Mr. Bates' new project has been submitted recently to the President and Secretary Taft. It would not be within the province of a medical journal to discuss the technical features of an engineering problem of this magnitude, but in so far as the methods concern the sanitary aspects of the situation, they are eminently fitted for medical comment. Two of the essential features of the plan are that Lakes Chagres and Panama should be enlarged so as to submerge the swamps around the terminal cities. "This," says Mr. Bates, "must have most

beneficial effects upon the health of the engineering and construction forces, and upon the residents of the cities for all time." "There will," he goes on to say, "be no more wading in saturated stifling jungles, there will be much less vegetation, and the mosquitos as a pest could be more easily controlled." As to whether the scheme set forth by Mr. Bates is feasible, economical, or practicable, no opinion can be expressed here, but if it be so and will improve the sanitary conditions, it should be worthy of consideration.

News of the Week.

Yellow Fever at Panama.—The recent outbreak of yellow fever at Panama appears to have been largely due to the incompetence and obstructive policy of the members of the late commission of unhallowed memory. It is asserted by Government officials in Washington that the fever never would have gained such headway had energy been shown in constructing proper quarters for the unacclimated Americans. The employees have been using the unsanitary old buildings. The center of the epidemic was in the main Government building, occupied by Gov. Davis, where it started. The victims were clerks in the offices. The building has been fumigated and the new commissioners have sent the lumber so that construction on the new buildings has been begun, and the epidemic, it is believed, is under control. Col. Gorgas, acting Governor and Chief Health Officer, reported, on May 12, that it had been nine days since a new case appeared, but since then there have been six. With Col. Gorgas now acting Governor and unhampered by the interference of Grunsky, there is reason to hope for improvement in the health conditions on the Isthmus.

The Efficiency of Quarantine at the Port of New York.—The Consulting Board of the Health Officer of the Port of New York, consisting of Drs. J. D. Bryant, E. G. Janeway, H. M. Biggs, G. L. Peabody, F. P. Kinnicutt, J. H. Girdner, J. W. McLane, R. H. Derby, Wm. M. Polk, J. W. Brannan, and T. M. Prudden, visited the Quarantine on Saturday, May 13, making a careful inspection of the station, hospitals, and laboratory. The Board passed a formal resolution of approval of the high standard of efficiency which is maintained by Dr. Doty in the administration of this important agency in the protection of the public health. The features which the Consulting Board regarded as especially noteworthy were the practical recognition of the fact that it is in the infected man and his immediate surroundings that danger lies, and not in the ship or its cargo or its healthy passengers; the systematic use of the clinical thermometer for the detection of early and obscure phases of infection; the application of scientific sanitary measures adapted to each special form of infectious disease; the liberal and humane efforts to ameliorate the hardships of necessary quarantine detention; and, finally, the unwearied efforts, through laboratory research and experiment, to add to the knowledge of useful, practical sanitation. Each year, the Board stated, the country is more effectively protected against the entrance of communicable and other infectious diseases, while at the same time there is a steady reduction of the annoyances to individuals and damage to commerce in which earlier quarantine systems were constantly involved.

The American Therapeutic Society.—At the sixth annual meeting of this society held in Philadelphia, May 5 and 6, the following officers were elected: *President,* Dr. Carl Beck of New York; *Vice-Presidents,* Drs. J. N. Hall of Denver and John V. Shoemaker of Philadelphia; *Secretary,* Dr. Noble P. Barnes of Washington; *Treasurer,* Dr. John S. McLain of Washington; *Recorder,* Dr. William M. Sprigg of Washington; *Curator,* Dr. George C. Ober of Washington.

Tuberculosis Among Negroes.—The high death rate from tuberculosis among negroes, the causes and effects of this disease, and the best means of combating and preventing it were discussed at a conference called by the committee for the prevention of tuberculosis of the Charity Organization Society, held in the assembly hall of the United Charities Building last week, under the presidency of Dr. Andrew H. Smith. Addresses were made by Miss Lilian Brandt, Dr. S. A. Knopf, and Dr. W. A. Brooks. The latter, a member of that race, said that the deplorable condition of the tenements occupied by the negroes in New York was largely responsible for the prevalence of consumption among them. Resolutions were passed recommending that active steps be taken to educate the negroes of New York City in regard to tuberculosis, and that a committee be appointed to cooperate with the committee on the prevention of tuberculosis of the Charity Organization Society to bring about the desired ends.

The Memorial Institute for Infectious Diseases of Chicago has established a Serum Division as a branch of its scientific and experimental work. This division will undertake the preparation of various sera and will also prosecute investigation into some of the problems of immunity and serumtherapy. Professor Edwin O. Jordan of the University of Chicago has been placed in charge of the Serum Division, and preparations for the new work are now well under way.

Cincinnati Academy of Medicine.—Dr. G. A. Fackler read a paper on May 8 on Cerebrospinal Meningitis. He reported eight cases treated at the Cincinnati Hospital in which the death rate was 50 per cent. The cases were remarkable in the absence of fetechiæ and any pronounced opisthotomes; Kernig's sign was present in all cases.

American Laryngological Association.—The twenty-seventh annual meeting of this association will be held at the Hotel Chelsea, Atlantic, City, N. J., on June 1, 2, and 3, under the presidency of Dr. Clarence C. Rice. The secretary is Dr. James E. Newcomb, 118 West 69th street, New York City.

Medical Legislation in Illinois.—The following bills of interest to the members of the medical profession, were passed by the House and Senate of the Forty-fourth General Assembly of Illinois. A bill prohibiting the embalming or preparing for transportation of dead bodies except by persons licensed by the State Board of Health, and providing for examination and license; a bill placing the employees of State charitable institutions under civil service rules; a bill empowering overseers of poor to provide treatment for patients afflicted with rabies, under the direction of the State Board of Health, appropriating $2,000; a bill providing for the location, erection, and maintenance of a State sanatorium for consumptives, appropriating $25,000 for this purpose; a bill providing for the sale and free distribution of diphtheria antitoxin under the direction of the State Board of Health; a bill placing physicians and nurses of the Cook County Hospital under civil service rules; a bill establishing a State Board of Examiners for Nurses, and providing for examination and license; a bill creating a State Board of Dental Examiners, and providing for the regulation of the practice of dentistry. The Legislature adjourned on May 6, *sine die,* without passing the

six osteopathic and two optometry bills, and one antivivisection bill, introduced since February 1. The Expert Witness Bill, providing that physicians attending court as expert witnesses shall be entitled to receive the sum of $10 only for each day's attendance, did not pass. The bill was vigorously denounced by the medical profession.

Defective Eyesight of New York School Children.—At a meeting of the Society of Medical Inspectors of the Health Department on Tuesday evening of last week, Dr. John J. Cronin, Chief of the Division of School Inspection of the Department of Health, read a paper in which he reported on the results of the new system of physical examination of school children. The new system went into effect in March; before that the work of the Health Department Inspectors dealt merely with the spread of contagious diseases. From March 27 to April 28, under the new system of thorough individual examination, 7,166 school children were examined. Of this number no less than 1,273 were unable to read the large letters at a distance of twenty feet, and about 33 1/3 per cent. of all those examined had defects of vision, interfering with the proper pursuit of their studies. Of these, a large number have procured glasses. This has already resulted in an improvement of the schoolwork, as borne out by the teachers' reports.

The New York Red Cross Branch.—The organizers of the New York State branch of the American National Red Cross held their first meeting at the home of Whitelaw Reid, one afternoon last week, and elected the following officers: *President,* Col. William Cary Sanger, ex-Assistant Secretary of War; *Vice-President,* Elihu Root, ex-Secretary of War; *Secretary,* Mrs. William K. Draper; *Treasurer,* Jacob H. Schiff. In the absence of Surgeon-General Van Reypen (retired), chairman of the central committee of the organization, Miss Mabel T. Boardman, a member of the committee, gave the address of the meeting and told the purpose of organizing the State branches. She explained that in the new articles of incorporation, State and Territorial branches must be organized as soon as possible, and that these branches must in their turn organize sub-branches, so that it will be like a great army with divisions into State militias, composed of companies organized throughout the State.

Death of the Last Survivor of the War of 1812.—Hiram Cronk, the sole survivor of those who fought in the American army in the war of 1812, died at Avon, N. Y., on May 13, at the age of 105 years He was born in 1800 and served as a volunteer in the defense of Sackett's Harbor from August 4 to November 16, 1814. For the last thirty or forty years he is reported to have been an inveterate tobacco chewer and an habitual, though temperate, wine drinker.

A Reunion of the Class of '95 of the Medical Department of the New York University was held at the Hotel St. Regis on May 9, the tenth anniversary of graduation. Dr. Eben Foskett presided and speeches were made by a number of the class members. It was decided to hold another reunion at the end of five years, in the spring of 1910.

For a New Hospital on the East Side.—Persons interested in founding a new hospital in the most densely crowded district of the East Side—the district between Houston and Fourteenth streets, the Bowery and the East River—had a hearing last week before Dr. Stephen Smith, Vice-President of the State Board of Charities, sitting as a Commissioner for the Supreme Court to determine the legality and propriety of the application. The hospital will be under Hebrew control and will be called the Beth Jacob Joseph Hospital.

Aldermanic Solicitude for the Little Ones.—At a recent meeting of the Board of Aldermen of New York, Vice-President Sullivan offered a resolution, which was adopted, calling on the Department of Health, the Charities Department, and the Tenement House Department to examine and report on the growing custom of landlords to refuse to rent houses and apartments to people who have children. The departments also were requested to get an opinion from the Corporation Counsel to see if the landlords could not be curbed in their race suicide proclivities, by the Aldermanic power. After considerable debate the board adopted the adverse report of the Finance Committee on the appropriation of $1,000,000 for playgrounds for the public schools.

A Nurse's Suit Against a Physician.—A trained nurse who sued a physician for defamation of character recently got a verdict for $250 in a Cambridge, Mass., court. The plaintiff alleged that the physician had publicly and maliciously stated that she was responsible for the death of several patients, through neglect. The defendant asserted that he was privileged as a physician to make statements about a nurse. He had been asked about the plaintiff and had honestly replied that he did not care to recommend her.

New Trustees for Roosevelt Hospital.—Gov. Higgins has signed Assemblyman Agnew's bill providing for the election of two additional trustees of Roosevelt Hospital from native born citizens resident of New York City.

A New Military Medical Attaché with the Russian Army.—Russia has granted the request of the United States that Brigadier-General Thomas H. Barry, Captain Sydney A. Cloman and Colonel John Van R. Hoff be allowed to go to the front as military attachés with the Russian army in Manchuria. Colonel Hoff relieves Colonel Howard of the Army Medical Corps who was captured by the Japanese on the retreat of the Russians from Mukden.

The Army Hospital Drill in the State Militia.—Adjt. Gen. Henry issued an order on May 13, adopting for the State National Guard the revised system of drill regulations for the regular army Hospital Corps, approved by the Secretary of War last October.

Meningitis in Germany.—The *Deutsche medicinische Wochenschrift* of May 11 states that the number of cerebrospinal meningitis cases in Upper Silesia in April was about 1,200. The deaths are roughly given as half that number.

Meningitis in Ireland.—Sixty cases of what is supposed to be meningitis have been reported from one district in County Down.

Synthesis of Adrenalin.—Reports from London state that much attention is being attracted by an article in the *Journal of Physiology* in which H. D. Dakin of the Lister Institute asserts that he has discovered a method of producing adrenalin from coal tar products.

Nebraska State Medical Association.—At the session of this society held in Beatrice, Lincoln was selected as the next place of meeting, and the following officers were elected: *President,* Dr. A. F. Jonas, Omaha; *Vice-Presidents,* Dr. Farley of York, and Dr. Spalding of Omaha; *Recording Secretary,* Dr. A. D. Wilkinson of Lincoln; *Corresponding Secretary* and *Librarian,* Dr. H. W. Orr of Lincoln; *Treasurer,* Dr. A. S. von Mansfelde, Ashland; *Delegate to American Medical Association* at Portland,

Ore., Dr. I. N. Pickett of Odell. Dr. A. S. von Mansfelde of Ashland was reelected *Chairman of the Committee on Public Policy and Legislation* and he appointed as members of the committee Dr. G. H. Brash of Beatrice and Dr. W. D. Shields of Holdredge.

Windham County (Ct.) Medical Society.—The 112th annual meeting of this society was held at Willimantic, and the following officers were elected: *President,* Dr. C. C. Gildersleeve, East Woodstock; *Vice-President,* Dr. R. C. White, Willimantic; *Clerk,* Dr. James L. Gardner, Central Village; *Censors,* Dr. J. B. Kent, Putnam; Dr. George W. May, Willimantic; Dr. A. E. Darling, Killingly; *County Reporter,* Dr. Charles M. Knight, Chaplin.

Gallia County (O.) Medical Society.—The annual election of officers for this society held at Gallipolis, resulted as follows: *President,* Dr. J. B. Alcorn, Gallipolis; *Vice-President,* Dr. William Miller, Vinton; *Secretary,* Dr. William H. Pritchard, Gallipolis; *Treasurer,* Dr. Ella G. Lupton, Gallipolis; *Board of Censors,* Dr. C. G. Parker, Gallipolis; Dr. S. W. Williams, Mercerville, and Dr. W. E. Howell, Rio Grande; *Delegate to the Meeting of the Ohio State Medical Association,* Dr. C. G. Parker; *Alternate,* Dr. W. H. Pritchard.

International Congress of Radiology.—The Belgian minister has submitted to Mr. Loomis, the Acting Secretary of State, a notification of the first international congress for the study of radiology and ionization to be held at Liège from September 12 to 14, of this year, under the auspices of the Belgian Government. Certificates of appointment as delegates from this country are to be issued by the State Department to any persons nominated by Secretary of the Department of Commerce and Labor. The delegates do not receive compensation and must pay their own expenses. The committee in charge, which is recruited from the faculties of the four universities of Belgium and the Military Academy, has framed the following program: (1) Physicochemical section: (a) properties of the electrons and accompanying radiations, *x*-rays, cathodic rays, ionization; (b) radioactivity and corresponding transformations; (c) meteorological and terrestrial phenomena connected with ionization and radioactivity; (d) *n*-rays. (2) Biological section: physiological properties and medical applications of the various radiations and of radioactivity.

Post-Graduate Hospital Subscription.—At the annual meeting of the faculty of the Post-Graduate Medical School and Hospital it was announced that the members of the faculty had pledged themselves to raise, before next Thanksgiving, $40,000, to go toward completing the sum of $100,000, which must be secured by popular subscription in order to obtain an anonymous gift of the same amount recently promised to the institution. Dr. D. G. St. John Roosa was reelected president; Dr. James N. West was elected secretary to succeed Dr. Forbes Hawkes, resigned.

Obituary Notes.— Dr. Alexander W. Rogers, the oldest physician in Paterson, N. J., and the oldest graduate of the New York College of Physicians and Surgeons, died on May 14. Dr. Rogers was born in Armagh, Ireland, in 1814. He was graduated from the College of Physicians and Surgeons in 1836, and from the following year practised medicine in Paterson. He was one of the founders of the Passaic County, N. J., Medical Society, and was for many years chief of staff of the Paterson General Hospital.

Dr. Oliver Woodson Nixon, for many years associated with the Chicago *Inter-Ocean* as literary editor, is dead at Biloxi, Miss. Dr. Nixon was a member of General Pope's staff, having been medical director of the army of Missouri.

Dr. Heber N. Hoople of Brooklyn died May 8, at the age of 49 years. He was a graduate of the Bellevue Hospital Medical College in the class of 1885.

Dr. Henry P. Merrill of Portland, Maine, died May 11, aged 62 years. He was born in Oxford county and came to Portland when a young man. He was a graduate of the Harvard Medical School in the class of 1867. For several years he was a member of the pension examining board. A wife and several children, including Dr. H. P. Merrill, Jr., of Portland, survive.

Dr. Francis Wayland Campbell of Montreal died May 4, after a long illness. He was born in Montreal on November 5, 1837. He received his early education at the city public schools, and in 1860 he graduated from McGill University with the degree of M.D. Shortly afterwards he made a tour of the large hospitals, successfully passing the examination of the Royal College of Physicians, London, and later he was elected a member of the Royal Medical Society of Edinburgh. He returned to Canada in the fall of 1861, and at once began the practice of his profession. He was one of the organizers of the medical faculty of Bishop's College, founded in March, 1871, of which he was appointed first registrar, and professor of the institutes of medicine. He filled the chair of psychology for ten years, and was elected professor of medicine, and dean of the faculty. He was one of the editors of the *Canada Medical Journal* from 1864 to 1872, when he established the *Canada Medical Record,* and remained its editor for many years. He was secretary of the College of Physicians and Surgeons of the Province of Quebec for ten years. For over forty years he served on the medical corps of the Canadian Militia, and was retired in 1898 with the rank of surgeon lieutenant-colonel.

Dr. Gideon A. Weed, a pioneer physician of the Pacific Coast, and a man who, as twice Mayor of Seattle, and a prominent citizen of Washington State, did much toward the upbuilding of the Northwest, died at his home in Berkeley, Cal., on April 21. He was born in New Providence, N. J., in 1833 and was graduated from the Rush Medical College, Chicago, in 1856. He went to the Pacific Coast in 1858, and practised in various places in California, Nevada, Oregon, and Washington. For ten years during his stay in Washington he was a Regent of the university, first the Territorial, and later, the State University. He helped to organize the Medical Society of Washington and the State Medical Board, besides carrying through much pioneer medical legislation needed in the new State.

Dr. Constant Henotte of Lowell, Mass., died May 6. He was born in St. Cesaire, Canada, in 1844, and was graduated from the Medical Department of Laval University, Quebec, in 1867.

Dr. Robert M. King of St. Louis died May 2, at the age of 62 years. He was born in Madisonville, Ky., and was graduated from the Jefferson Medical College, Philadelphia, in the class of 1867. He went to St. Louis in 1876. He was one of the founders of the Beaumont Medical School, now the Marion Sims College of Medicine. He was treasurer of the St. Louis Medical Society.

Dr. George N. Watier of Stillwater, Minn., died May 1, at the age of 48 years. He was born in Canada and was graduated from the Trinity Medical College, Toronto, in 1883. He had practised in Stillwater for about eight years.

Correspondence.

SPINAL IRRIGATION IN CEREBROSPINAL MENINGITIS.

To the Editor of the Medical Record:

Sir—I would suggest to those having laboratory facilities to test the practicability of irrigating the craniospinal cavity by a combination of dural with lumbar puncture. If found practicable it might prove useful in the treatment of cerebrospinal meningitis. Andrew H. Smith, M. D.

New York, May 15, 1905.

BLOODLETTING IN CEREBROSPINAL MENINGITIS.

To the Editor of the Medical Record:

Sir—Having had experience with two epidemics of cerebrospinal meningitis, one in the southern part of this State in the early sixties, the other in this city a few years later, I am prompted to refer to the benefits of general bloodletting. At first I adopted mild antiphlogistic treatment, general and local. Results were not entirely satisfactory. It then occurred to me that thickening of the membrane within the unyielding bony canal and consequent pressure must of necessity cause some, at least, of the symptoms presented, and that the most rational treatment would be to relieve the pressure by venesection. I accordingly bled my next patient, resulting in marked improvement. But the symptoms soon recurred. I then bled to the extent of producing syncope. The patient made a rapid and uneventful recovery. Afterward I bled to syncope at first, and repeated as often as the symptoms, especially the opisthotonos, returned. I have thus repeated the venesections three or four times, by reopening the same orifice, in much less than so many days.

I am aware that in the light of prevailing atmospherical conditions this letter may have a sanguinary tinge, but patients so treated almost invariably recovered, and without sequences. A. G. Field, M. D.

Des Moines, Iowa.

OUR LONDON LETTER.

(From Our Special Correspondent.)

DIABETES MELLITUS—DISSEMINATION OF MAMMARY CANCER—PERIODICITY IN JOINT AFFECTIONS—PREHISTORIC VESICAL CALCULI—[illegible]

London, April 28, 1905.

The Goulstonian lectures at the College of Physicians were this year delivered by Dr. Cecil Bosanquet, who devoted these to some considerations on Diabetes Mellitus. The nature of the disease as opposed to mere glycosuria he attributed to internal formation of sugar from the tissues of the body, the liver having nothing to do with this condition, though possibly aggravating symptoms by temporary increase of sugar existing in the blood and passing thence into the urine. The reasons for attributing diabetes to defect of the pancreas and its possible interaction with other organs, were then considered at length. As to the source of the sugar, Dr. Bosanquet suggests that a number of indications point to the disintegration of fat, from which the two substances most characteristic of the disease might be derived—the acetone bodies from the fatty acid, the sugar from the glycerin radicle. The hypothesis is certainly speculative, but seems deserving of consideration. No one doubts that the pancreas has something to do with diabetes; indeed, it is probable that in all cases there is disease of that organ—the islands of Langerhans being the exact seat of the lesion. We may suppose that the pancreas can supply a substance necessary for the assimilation of sugar by the cells of the body, but there is no evidence in support of such a supposition. It seems more likely that it could counteract some poison which causes accumulation of sugar in the blood. The results of experiments with suprarenal extract and phloridzin and compatible with this conjecture. If Dr. Bosanquet's views prove correct, the earliest stage of diabetes would be a predisposing cause of glycosuria, rather than its actual cause; for at first the breaking up of tissue cells might not more than meet the sugar-assimilating power of the system. But then a slight increase of saccharine food might produce glycosuria. So a slight nervous shock might liberate enough glycogen from the liver to augment the sugar in the blood in the same degree. So we may possibly come to define diabetes as an increased internal dissociation of tissue (possibly fat) into sugar, caused by a toxin produced in normal metabolism and normally neutralized by the pancreas.

Professor Sampson Handley, in his Hunterian lectures on the "Dissemination of Mammary Cancer," brought out a point of great importance from a surgical aspect. He points out that the lower and inner margin of the breast overlies the sixth costal cartilage and is only about an inch from the interspace between the ensiform and the seventh cartilage. Thus as soon as parietal permeation has extended an inch beyond the edge of the breast the cancerous lymphatics of the deep fascia are separated from the subserous (subperitoneal or sub-pleural) fat by no more than a single layer of fibrous tissue traversed by lymphatic channels. At the tip of the ensiform cartilage the transversalis fascia is hardly recognizable as a distinct layer, and the parietal lymphatic plexus is separated from the subperitoneal fat simply by the linea alba. Through this weak spot cancer may reach the peritoneum before it can the well protected pleura. The natural conclusion from this is to extend operations beyond removal of the breast and axillary glands by removing also as wide an area as possible of the deep fascia. To prevent "epigastric invasion," the usual incision should be prolonged downward over the linea alba for about two inches, the flaps undermined, and the fascia excised as far down as a horizontal line running two inches below the ensiform cartilage, or even lower if the growth is in the inferior part of the breast. Prof. Handley has not found this step increases shock. Excision of overlying skin and underlying muscle must be free, but need not extend over so wide an area as excision of fascia, as extension to skin and muscle is a secondary process. The professor thinks the extension of the operation he now advocates will bring about a further reduction in mortality. In this he is supported by the fact that local and intrathoracic recurrences are more rare since the modern adoption of wider operations. These seem to afford the chest a maximum of protection, but abdominal recurrence is not so well prevented, and Prof. Handley is convinced that a recognition of the danger of epigastric invasion and the adoption of the operation he suggests to prevent it will bring about an appreciable reduction in the mortality of mammary cancer.

Periodicity is rather an attractive phenomenon for study, as the cases in which it is most marked are various and its appearance in some of them contradictory of the explanations that have been offered. Malaria, of course, suggests itself when any case assumes a distinctly periodical character, but is to be regarded as an unsatisfactory explanation unless the parasite is detected. Mr. Howard Marsh related a case of joint disease to the Clinical Society which in default of other explanation he termed malarial. A man of 38, with a history of both syphilitic and malarial infection, was attacked with severe pain in the knee without swelling or loss of movement except in the attacks, which came on every evening, subsiding gradually. During the swelling the knee measured 1½ inches more than its fellow, the shape being globular. No fluid seemed present in the joint, and the swelling was attributed to vascular turgescence of the synovial membrane. The blood was examined by Major Ronald Ross, but no parasites were found. The patient recovered under quinine. Six months later he had a patch of swelling over the internal malleolus, with hyperesthesia of the skin over it. This also was relieved by quinine.

Sir P. Manson could see no reason for ascribing the disease to malaria. The periodicity was quotidian, which is common to various conditions as to all septic fevers. Evening exacerbations are common in syphilis, but rare in malaria, in which the typical feature is the occurrence before mid-day. There was no affection of the spleen or fever. The blood examination was after the quinine, so of less value than if previously.

Lieutenant-Colonel Mulroney had seen many cases of malaria complicated with syphilis temporarily relieved by quinine, but to cure, iodide must be given as well.

Mr. Marsh then gave an account of three cases of intermittent hydrops of joints. In all three, effusion returned periodically; in two every fourteen days, in the other every twelve. The local condition was merely increase of synovial fluid. In the intervals the joints were normal. The cases resembled those described by Drs. Brackett and Cotton in 1901 in the *Boston Medical and Surgical Journal*. The intervals in those cases varied from three or four to thirty days, the most common being fourteen. In several instances attacks continued three, four, or more years. The pathology was unknown. Possibly a vasomotor disturbance was concerned. Arsenic was the only drug that had been thought of use, as some cases improved under it, but then spontaneous recovery was common enough, leaving the treatment doubtful. These cases might lead to error by suggesting a loose cartilage or synovial fringe, for which a useless operation might be undertaken.

Mr. Wallace thought such cases microbic, and suggested cultures from the fluid; but as to this Dr. Poynton pointed out that in joint affections microorganisms were commonly confined to the subendothelial layer and seldom found in the fluid. He suggested that the cases were rather of the

nature of edema or urticaria. Subcutaneous injections of sera had been known to produce synovial effusion.

Dr. Forbes-Ross looked upon serous effusion as due to want of coagulability of blood, as in malaria or after taking mercury. Mr. Marsh replied that the cases did not seem infective, as there was no structural change. Dr. A. E. Garrod had told him he had seen such cases follow gonorrheal rheumatism.

Professor Elliot Smith presented to the Hunterian Museum a calculus which he found in the prehistoric cemetery at El Amrah, in Upper Egypt, and this interesting object was shown at the Pathological Society on the 4th inst. It was found between the innominate bones considered as those of a boy of about 16. It consists of uric acid encrusted with phosphates. The usual yellow crystals in columns are seen on section, and the usual matrix is also present, but there is no oxalate of lime. Neither is there any indication of bilharziosis, which, so far as this shows, may not have been prevalent at that early period. Prof. Elliot Smith estimates the age of this calculus as at least 7,000 years. Mr. Shattock, who showed the calculus, said he had had the opportunity of examining another from a tomb of the second dynasty in a cavity in which were the coccidia of a mould, so natural in appearance that attempts were made to cultivate them, but without result. It was found by Dr. Reisner for the California University's expedition.

The approaching visit of medical men to Paris promises to be a success, and is looked forward to with anticipations of pleasure and instruction. Arrangements are completed for visits to some of the French spas, where entertainments are promised to those who make the excursions.

The treasurer of Guy's Hospital acknowledges a donation of £5,000 from a friend as a thankoffering and an encouragement to others. The committee of the Ophthalmic Hospital has received £5,324 in response to its appeal for £50,000 as its centenary fund. It is promised that this fund shall be invested to meet the demand of £1,200 a year for ground rate, and, secondly, towards the heavy rates. The committee, perhaps, by this time may be realizing the folly of having sacrificed its property in Moorfield for the costly building incumbered with such a ground rent. The appeal for St. Bartholomew's Hospital is being advertised in a way which elicits protests in various directions. Old Bart's men are indignant to see their hospital issuing advertisements which in the case of small institutions would be pronounced disgraceful.

Dr. Thomas Trollope died on Good Friday, aged 75. He was senior physician to the St. Leonard and Sussex Hospital, which he had served for about forty years. He was a Cambridge graduate, B.A. and M.D.

Sir John Sibbad, M.D., F.R.S.E., late commissioner in lunacy for Scotland, died on the 20th inst., aged 72. He was formerly joint editor of *The Journal of Mental Science*, to which he contributed various papers.

OUR BERLIN LETTER.

(From Our Special Correspondent.)

AN ALLEGED PROTOZOAN PARASITE IN SYPHILIS—CEREBRO-SPINAL MENINGITIS—POISONING BY A SULPHURETTED HYDROGEN PREPARATION—HOSPITAL FOR THE TREATMENT OF VENEREAL DISEASES.

BERLIN, April 8, 1905.

JOHN SIEGEL recently read a paper before the Reichsgesundheitsampt, in which he discussed his researches in regard to syphilis. The work of Ross on the plasmodium of malaria suggested to Siegel the idea of studying the acute exanthemata by zoological methods. After spending several years at this work under the direction of our well-known zoologist, F. E. Schultze, he found in smallpox, scarlet fever, and syphilis, parasites which probably all belonged to the same class of protozoa. In the early stage the microorganism is motile. It is 1 μ long, and has a movable flagellum and two nuclei, surrounded by very bright protoplasm. It takes the blue stain readily. At a later stage the nuclei subdivide, while the protoplasm grows. The two neighboring nuclei unite to form a new protozoan. The mother cell produces a great many of these. In smallpox, the parasite always lies in the protoplasm of the epithelial cells. In syphilis, the protozoa are found in the connective tissue of the vessels. Siegel claims to have infected small animals, such as rabbits, with this disease, by injecting the iris with the liquid taken from condylomata of syphilitic men and with the blood of rabbits which have previously been infected. Siegel believes these microorganisms to be protozoa because the two nuclei and the movable flagellum occur also in other flagellates; the very bright protoplasm resembles that of the trypanosomata; they are not bacteria on account of the nuclei which color so readily; examination by ultra-violet light indicates that the nuclei are composed of chromatin. The objection may be raised that these bodies cannot be protozoa because they do not die in glycerin and water. But the resistance of protozoa to different chemicals is proved by the fact that the plasmodium malariæ is not destroyed in the stomach and intestines of the anopheles and by the fact that *Haemogregarina stepanovii* lives for a long time in the intensely acid gastric liquid of the leech, without restriction of later growth.

Recently, the ophthalmologist Schultz has published his researches, which were undertaken in accordance with Siegel's method. After opening the anterior chamber of the eye, the iris is scratched and rubbed with an emulsion consisting of bits of the primary sore in equal parts of water and glycerin. In this way Schultz has operated upon fourteen rabbits. Four others were infected with the kidney tissue of rabbits whose iris had been previously infected in the manner just described. And one rabbit was infected with the blood of a man recently infected with syphilis. In most of the cases, the blood, kidneys, and spleen of the rabbits, after they were killed, were examined, and in every case was found the *Cytorrhyctes luis*. The eyes were hardened in absolute alcohol and the anterior part of the bulb was imbedded in paraffin. Sections 5 μ in thickness were made because the organism cannot be seen in thicker sections. The organism appears in greater numbers when the emulsion is a very fresh one. When the emulsion is older, only a few organisms are found, and then after long searching. The best method of staining is the following: First, hematoxylin is used for a few minutes, according to the thickness of the specimen; this is followed by acid alcohol, which decolorizes, after which the specimen is washed in distilled water and is then colored with azure II, 1: 1,000, for from two to five hours. The specimen is then quickly dipped into alcohol, 93 per cent., and xylol, and mounted in Canada balsam. The azure solution should be boiled every time it is used, and then filtered through two layers of filter paper.

All Germany is alarmed on account of the presence of epidemic meningitis. This disease, which for nine years was nearly extinct, has now spread over all Germany. It has found the greatest number of victims, however, in Silesia. There are now in Berlin three cases. The government has sent a health officer to Silesia to study the disease.

Stadelmann read a very interesting paper before the Berlin Medical Society recently. He showed a preparation which he had made by introducing sulphuretted hydrogen into caustic lime, which is used as a depilatory. A girl eighteen years old swallowed this powder. She was admitted to the hospital. There were cyanosis, small pulse, clonic spasms, vomiting, and unconsciousness. The tongue and pharynx were covered with ulcerations; the urine contained casts, albumin, and blood. After her recovery, which took place gradually, the patient said that she had taken only one spoonful of the powder. Sulphuretted hydrogen developed in the stomach. The substance affects chiefly the nervous system. Treatment consisted in washing out the stomach, and in the administration of laxatives and restoratives.

The hospital for the treatment of venereal diseases, so long needed in Berlin, is now about to be built. Up to this time there has been no special hospital for these diseases. The Urban Hospital was the first which had a department for such troubles. The new institution is to be built in a very short time in Rummelsburg, a suburb of Berlin.

Landerer, who died about six months ago, has been succeeded by Kausch, formerly assistant to Miculicz in Breslau.

The Treatment of Intestinal Paresis.—Dahlgren says that in cases of general peritonitis in which eventration is necessary he has found the following procedure very useful. The middle portion of the intestine is brought over to the left side and an incision from 1 to 1 1-2 cm. long is made into it, the edges of the cut being kept open by artery clamps. Beginning on either side of this the intestinal contents are "milked" out either with the finger or by means of a special double roller of the author's invention. The process is continued until the volume of the intestines has been reduced sufficiently to permit of their easy return to the abdominal cavity. By this manipulation the danger of postoperative atony is much reduced and the patient's condition is also greatly improved by having a large quantity of noxious material removed from the system. Dahlgren also commends milligram doses of atropine given hypodermically for postoperative atony. Several cases are described in which the paretic condition of the gut was relieved by this treatment and even though from five to seven milligrams of the drug were administered in the course of from twelve to fifteen hours no symptoms of poisoning were produced.—*Zentralblatt für Chirurgie.*

Progress of Medical Science.

Boston Medical and Surgical Journal, May 11, 1905.

Some Suggestions in Regard to the Diagnosis of Seminal Vesiculitis. [illegible] tabulates the urinalysis findings in nineteen cases. The common signs of seminal vesiculitis are distention of the vesicle, its thickening or stiffening, and tenderness of the structure and of surrounding tissues. The most reliable evidence is based on the results of examination of the vesicle contents. In order to show that a purulent exudate exists within it, we must eliminate as far as possible the admixture of pus and bacteria from the urethra and prostate. The technique adopted to secure the uncontaminated vesicle product is thus described: Patients are instructed to come with a full bladder, and this is first [illegible] urethra. The urethra is then irrigated with boric [illegible] and 4 or 5 oz. allowed to run back into the bladder, which is then emptied. In this way the urethra is rendered as clean as possible. The bladder is then again distended with boric acid or salt solution and the prostate [illegible] leaving the region of the vesicle undisturbed. A [illegible] unt of prostatic fluid can be expressed so as to flow from the meatus, but this is not to be regarded as the whole expressed contents, as a certain amount will flow back into the bladder, depending, probably, upon the condition of the posterior urethra. If now the patient empties his bladder, as much has been done as possible to eliminate [illegible] the bladder is then a third time distended and the vesicles massaged, expressing the contents as thoroughly as possible. By this massage a variable amount of vesicular contents is expressed so as to come out at the meatus, but in many cases the major portion of it runs back into the bladder and is passed when that viscus is emptied.

[illegible]

A Case of Digitalis Poisoning With Very Low Temperature Without Collapse: Recovery.—W. N. [illegible] reports [illegible] degeneration who took an undetermined amount of digitalis tincture, repeating the amount two hours later. A few minutes after the second dose she had a rather violent attack of vomiting and diarrhea, with severe pain in the epigastrium, radiating to the back. The vomiting and diarrhea did not occur. Pulse was 54 and respiration 94 degrees F. The latter continued for some hours, but there were no other symptoms of collapse—no air hunger, sweating or weak, thready pulse. The face was pallid, but the pulse was slow and regular. Under ammonia and whiskey stimulants, with extreme heat, recovery was prompt.

The Skiagraph of the Future.—According to J. Rudis-Jicinsky, the desideratum in skiagraphic work is the operation of the diffused rays throughout the mass of tissue interposed between the tube and the sensitive plate. The usual forms of apparatus, as the lead box, calcium lungstate, screens, etc., are clumsy or imperfect in intensification. The author has devised a "protector" which is a combination of a protective screen and shield, mask, and a lead box, with diaphrams and a metal cylinder and specula for precluding the diffused *x*-rays. The device may be used with great advantage in therapeutic work, in diagnosis, in fluroscopic examination, and skiagraphy, giving most excellent results not obtainable without it. During the whole exposure of a patient one may observe the tube in action anteriorly and posteriorly, without disturbing the patient. In this way not only is the patient protected in prolonged exposures, but the operator also is protected during such operations and for the future from medicolegal complications, because there is no burn possible.

Some of the Principles of Manual Therapy; Its Application by the Physicians.—J. P. Arnold calls attention to the neglect of manual therapy in medical practice. As an illustration of its value and ease of application he notes the fact that light continued pressure over the occipital nerves produces a peculiar quieting effect on patients, and they are inclined to sleep. Similarly it is found that pressure along the spinal column and in certain regions of the neck produces distinct changes in the circulation of the central nervous system. In the same way it may be shown, according to the author, that for many of the common affections there is a substratum of disordered circulation, and that the condition may be greatly ameliorated by pressure on the proper spinal segment. The author declares that brief pressure along the spine arouses the reflex constructor nerves and brings about a certain amount of contraction in the blood vessels of the skin and muscles of the back in the region treated. It also undoubtedly produces at the same time a certain amount of dilatation of the vessels in the cord. On the other hand, continuous pressure along the spine arouses the reflex dilators and brings about a certain amount of dilatation of the blood vessels of the skin and muscles of the back and a corresponding contraction of the blood vessels in the cord. Arnold makes a plea for the examination of the backs of patients. Many of the latter come complaining of some minor trouble, such as indigestion, constipation, etc., and if we examine the back in such cases we shall find some fundamental disturbance of the nervous mechanism controlling the part of the organism affected.

Medical News, May 13, 1905.

Treatment of Fulminating Appendicitis.—The paper of J. M. Inge is in general a plea for the more general adoption of the Ochsner treatment with the added recommendation of drainage by a small stab wound through abdominal muscles, transversalis fascia, and peritoneum to the mass of adhesions. If pus escapes we should use only a narrow strip of rubber tissue; if no pus, only serum, a small, loosely rolled gauze-wick surrounded by rubber tissue and not larger than a pencil. Whether pus or only serum escapes in small quantity at first, the capillarity is such that the flow of the infected material will certainly and promptly start in the direction of the drain and escape externally. Tissue pressure will force it along the line of least resistance, more especially so in cases of appendicitis where the muscles contract and are constantly rigid, much more so than in cases of salpingitis and ovaritis and other intra-abdominal inflammations; such drains will draw quarts of fluids from the abdominal cavity by capillarity.

American Medicine, May 13, 1905.

Surgical Intervention in Cases of General Peritonitis from Typhoid Fever and Acute Gonococcus Infection.—Joseph Price states that typhoid and other perforations are always followed by peritonitis, local or general. The possibility of its remaining local or circumscribed by adhesions should not be considered if the diagnosis of perforation has been made. The characteristic symptoms of typhoid perforation are sharp, sudden abdominal pains, collapse, nausea and vomiting in a good percentage of the cases, falling temperature early, followed by a rise in the temperature. Perforation and hemorrhage are the two accidents in such a case that are commonly anticipated. In more than 75 per cent. of the cases recorded, general septic peritonitis has been found with escaping bowel contents, gas and feces, foul pus, and free exudate in considerable quantity. The perforations are quickly and easily found near the ileocecal valve; rarely multiple or ragged. Whether of large or small caliber, fine pure silk is the safest material; the lumen of the bowel can be safely reduced one-half. The interrupted suture gives the best result and less risk of strangulation. If the margins of the ulcer are ragged they should be trimmed. A resection is an unjustifiable and dangerous procedure; simply anchor the ragged ulcer and disorganized bowel with catgut sutures on the opening between drains, forming an artificial anus or fecal fistula, which is a much safer procedure and is commonly followed by spontaneous closure. If this result does not follow, the fistula can be easily remedied after convalescence. The irrigation or wash toilet, so long practiced, has unquestionably given the best results. It should be a thorough cleansing with sterilized water—the entire surface, both the visceral and parietal peritoneum. Dr. Price believes irrigation with hot normal salt solution is harmful by irritation. Curetting or wiping dirty points with gauze is followed by good results. The gauze pack, so commonly and recklessly used, is a dangerous procedure favoring too many acute and chronic obstructions by pressure. Unless the operator understands how to place gauze drains or cofferdams in and about filthy surfaces, he would better fill the peritoneal cavity with hot salt solution and close.

Gallstone Obstruction of the Bowels.—Alfred C. Wood reports the case of a woman aged 58, operated upon for intestinal obstruction. The obstruction was found to be due to a gallstone in the ileum, six inches above the valve. The stone was removed through an incision. It weighed 11.6 gms., and measured 9.3 cm. by 8 cm. in circumference. A second stone, weighing 9 gms., was removed from the gallbladder through an incision over the latter. The patient recovered. Brief notes of 21 additional cases, collected from the literature of the past five years, are appended. Of these 22 cases, 12 patients recovered, and 10 died, mortality 47 per cent. But two of the number were men. The ages ranged from 31 to 73. The average of the women was 59.85 years. One-half of all the cases occurred in the sixth decade. The site of the obstruction was: Duodenum, 1; duodenojejunal junction, 1; jejunum, 2; "small intestine" (probably ileum), 1; ileum, 11 (probably 15); ileocecal valve, 1 colon, 1; not stated (probably ileum), 3. In one case the stone was in a mass of adhesions in the gallbladder region and caused obstruction by setting up a local peritonitis.

The Alleged Destruction of Red Blood Corpuscles in the Spleen.—Edward T. Williams gives a translation of Köl-liker's utterances on this subject, taken from his work on

"Microscopical Anatomy." Kölliker thinks that red blood corpuscles are not a natural element of the spleen, but result from hemorrhagic effusion. They then pass into dissolution. This occurs through the formation of large blood-corpuscle-holding cells, by the spontaneous development of an investing membrane round a clump of corpuscles and of a nucleus in the interior. The corpuscles immediately break up into pigment granules and soon disappear altogether. This is seen in almost all animals. The arguments pro and con are stated at length, and the author confesses that he was often tempted to abandon the theory and go over to the opposite view of Hewson, but always came back to his original opinion. In commenting on this theory, Williams declares that the idea of a perpetual splenic apoplexy affecting all animals throughout life without the slightest effect on their health is inconceivable. Moreover, the alleged effusion never clots, never distends the organ, never displaces the tissue fibers, and never excites inflammation. Kölliker failed to state his method of examination. He used no fixatives, and tacitly admitted that he examined some specimens in water. He used pathological and probably partly decomposed spleens. Scherer, as quoted by Kölliker, found putrefactive products in spleens, which could not have occurred had he used fresh specimens. Williams found dissolving blood corpuscles in specimens treated with water, salt solution, artificial serum, and to some extent in preparations fixed by heat and stained with watery solutions of the aniline dyes. Since he had used only fresh spleens fixed with sublimate-salt and stained with hematoxylin-casein he found none at all. Hence he was forced to conclude that Kölliker's theory was a chimera. Kölliker was a great anatomist, but not a great thinker. He is believed to have been mistaken in the present case.

Journal of the American Medical Association, May 13, 1905.

The Therapeutic Use of the X-Ray.—W. A. Pusey gives the results of his later experience with the *x*-ray. In some disorders, such as hypertrichosis and lupus erythematosus, the results have not equaled expectations; in some others, such as tubercular glands and joints and deep sinuses, the results have been variable, though with some marked successes. The value of the *x*-rays has been most markedly demonstrated in sycosis, tinea, acne, rosacea, lupus vulgaris, blastomycosis, cutaneous carcinomata and senile keratosis. The value of the *x*-ray has also been shown in hyperidrosis, inflammatory dermatoses, pruritus, nevi, keloid, sarcoma and as a prophylactic after operation for malignant disease. In some other conditions, abdominal tuberculosis, actinomycosis, mixed tumors of the parotid, there has been apparent benefit from the *x*-rays, but Pusey does not feel inclined, from his experience, to make and very positive generalizations. In the deeper situated cancers, as might be expected, the treatment is less hopeful, though palliation may be hoped for and some surprisingly good results are reported. In conclusion, Dr. Pusey gives his latest experience with pseudoleukemia, leukemia and goiter. In the former he has repeatedly seen clearing up of the glands, but in the only case he has been able to follow up there have been repeated recurrences. In true leukemia he has seen like good effects as regards disappearance of the enlarged glands, but generally without any corresponding improvement in the condition of the blood. One remarkably successful apparent cure is reported, the blood examination revealing normal conditions and the patient apparently well. In some small parenchymatous goiters he has seen reduction in size of the tumor, but in most of his cases no benefit was observed.

A Curative Serum for Typhoid.—W. R. Stokes and J. S. Fulton report the result of their experiments in the production of a curative serum for typhoid. Their experiments were made on guinea pigs and on rabbits with polyvalent serums derived from hogs. These serums were tested for agglutinative power, minimum fatal dose, protective influence and power of destroying the typhoid bacillus, either alone or mixed with other serums. Hemolytic experiments were also performed. The serum was tested clinically in twenty-three cases, two of which resulted fatally; it seemed to contribute to the favorable result in fifteen of the cases in which recovery took place. The clinical observations and the laboratory experiments alike indicated that the immune hog serum is not hemolytic for human blood. Stokes and Fulton conclude that by the use of this serum the febrile period may be shortened and the daily variation may be favorably modified.

Diagnosis and Treatment of Abdominal Pain.—J. B. Deaver insists on the importance of most careful study of every detail in cases with abdominal pain. The abdominal surgeon must, of all things, shun superficial methods in diagnosis, while at the same time delay in diagnosis must also be studiously avoided. Too early resort to exploratory operation after insufficient examination is also condemned, as is also too frequent palliative use of opium. The character of the pain, the patient's history, especially as to prior attacks, etc., the age and sex and occupation must all be considered. The location of the pain, especially in relation to nervous distribution, must be studied and the possibilities of referred pain from disorder in distant organs be kept in mind. Another matter of importance in abdominal pain is its diffuse or localized character, whether it is at first diffuse and later becomes local, or vice versa. Illustrations of all these points are given by Deaver. The differential diagnosis is of special importance in abdominal pain, and he here gives the list of the conditions that are most necessary to be distinguished from each other, among them the abdominal referred pain from thoracic disease, perforation, uremia, hernia, colic, calculi, movable kidney, the visceral crises of nervous disorders and of arteriosclerosis, ectopic pregnancy, etc., as well as appendicitis. One who closely studies his cases, even if an error is made, will be less to blame than one who jumps to a conclusion or who confessedly makes habitual resort to an operation to discover his patient's ailment. In considering treatment the cause of the pain must first of all be kept in mind. To remove the cause surgery is not always the only recourse. Dr. Deaver is strongly opposed to the use of opium in abdominal pain, only in exceptional cases just before operating for appendicitis and in far advanced cases of malignant disease does he consider it advisable. While other means than surgery, such as rest, position, attention to the condition of the digestive tract, regulation of diet, etc., will suffice in many cases, there are still the severer conditions requiring operation, and here the diagnostic ability of the surgeon comes into play. The reason why the surgeon is called on oftener to operate than to assist in the diagnosis is, Deaver says, his own fault and the result of the fallacious teaching of exploratory incision. Diagnosis should be the forerunner of operation; without a diagnosis operation should only very exceptionally be done. The importance of prompt diagnosis and operation is insisted on, and in some cases, such as probable perforation or abdominal hemorrhage, it may even be advisable before a certain diagnosis is made. Dr. Deaver is not a believer in last-resort operations, and even in chronic cases operation should not be left too long untried.

The Lancet, May 6, 1905.

General Septic Peritonitis in Typhoid Fever Without Evidence of Perforation of the Bowel.—C. G. Watson reports the case of a boy of nine years who on the tenth day of typhoid developed the general features characteristic of septic peritonitis. Abdominal incision was made and the abdomen cleaned out, the operation lasting only twenty minutes. Death came seven hours later. Autopsy revealed no perforation of the bowel and that none had taken place in the case seems probable on account of (1) the absence of free gas or intestinal extravasation; (2) the nature of the pus (and the probable absence of bacillus coli); and (3) the condition of the ulcers and the peritoneal coat. It seems not unlikely that this was a case of pure typhoid peritonitis, and had it been seen earlier might have been treated successfully.

Tetanus and Chloral Hydrate.—J. Maberly reports one case which is of interest in that chloral hydrate was the only drug used. His patient, who was a young man of twenty-one years, recovered after an illness of ten days. The case records show that sixty grains of chloral were given every four hours until two hundred and forty grains had been absorbed within eleven hours and that without any depressing effect on either pulse or temperature. The author regards this remedy and the poison of tetanus as directly antidotal. He suggests the advisability of commencing the treatment of an adult case of tetanus by doses of about thirty or forty grains of chloral hydrate and steadily increasing this to a drachm or more until the desired effect was produced, repeating the dose when the spasms recurred, and gradually reducing the quantity as the spasms became less violent in character. In this particular instance twenty grain doses had not the least effect, but sixty grains completely controlled the symptoms. It was possibly a favorable case for treatment, but it at any rate demonstrated the fact that chloral hydrate is a very antitetanic remedy and one well worth further investigation on the lines suggested.

Observations Upon the Blood.—Attention is called by C. W. Cunnington to the significance in blood examinations of granularity of the eosinophile cell. These granules are probably antitoxic or bactericidal in nature and are discharged into the blood at the onset of an infection and after the toxins have been neutralized the blood becomes richer in antibodies. The manner in which the granules steadily increase in number during convalescence strongly suggests the mode of action of a gland cell and its method of secretion. The author enters a protest against the present reliance on the leucocyte counts as an evidence of pus and says that a constipation lasting three or four days will send the count up to the pus level. "Woe betide you," says he, "if you enter an up-to-date surgical ward with a loaded cecum." Of course, a distinct value attaches to a series of

counts, but a single count is extremely fallacious. He summarizes by saying that when this cell is present to the extent of 1 per cent. or more it is almost certain that there is no active suppuration taking place. This cell may be quite absent although there is no abscess. In some cases of abscess there is no leucocytosis, but in these cases the eosinophile cell is always greatly diminished in percentage and is generally absent. Cases of chronic pyosalpinx frequently show no leucocytosis, yet the eosinophile percentage is very small, thus differing from cases of ovarian tumors. It is often asked, Why do some cases of suppuration give a leucocytosis and others not? Briefly the answer is that when pyæmic abscesses are being absorbed under pressure there is a high leucocytosis; when the fibrous wall of the abscess is so dense that very little absorption of toxins is taking place there is little or no leucocytosis; when pus is draining freely away the same absence of leucocytosis is found. But in both of these two conditions (conditions of suppuration without leucocytosis) the eosinophile cell is greatly diminished or absent. Hence the importance of paying attention to the *differential* as well as the *simple* blood count.

British Medical Journal, April 29 and May 6, 1905.

Remarks on the Etiology of Carcinoma.—George T. Beatson again advocates the "germinal theory" of cancer. He calls attention to the fact that under oöphorectomy, mammary carcinomatous tissue is very much influenced and may even disappear. The change consists in the great increase in the stroma of the growth, and a marked disappearance and fatty degeneration of the epithelial cells. If this theory is correct, he believes that there ought to be found nuclear protrusions (polar bodies) and fewer chromasomes in the so-called germinal cells. These phenomena have been proved by Farmer, Moore and Walker. The characteristic feature of cancerous tissue is the disorderly distribution of its large, irregular and polymorphic cells. The carcinomatous cell is unirritating in character. Constitutionally, the cancer cell gives no sign, and this is the cause why so many malignant growths run a long course before they are observed. As has been mentioned, there exist in malignant growths special cells characterized by a reduced number of chromasomes which have their type in the reproductive cells of the body. The writer thinks that from this it would almost seem that through some functional inactivity or disease in the testes or ovaries, the part affected by the carcinoma is doing their work vicariously, or helping them in an excess of work thrown upon them. He further suggests that it is possible that the body tissues elaborate the procreative fluid. In this case, the possibility of this interchange, and the necessity for assistance in their work, is not unlikely. The writer believes that the "germinal theory" harmonizes best with the facts and course of the disease as observed clinically, and explains many obscure points. It assumes the existence of a general tissue secretion. With such a procreative fluid in the body, if the testes or ovaries through functional decay or disease are unable to deal with it, it is possible that tissues or organs that have retrograded physiologically may take upon themselves the function of secreting it. The writer holds that the masses of the tumor cells do not constitute a tissue at all, but are thrown off by altered somatic cells in the elaboration of the special secretion. If this is true, then in carcinoma, we have a tissue secretion to deal with, in relation to which the fat probably acts like a middleman. If this theory is true, the therapeutic outlook should not be too pessimistic.

Cinnamic Salts in the Treatment of Cancer.—Lovell Drage in his discussion of this drug states that he gives it by the subcutaneous injection of a 10 per cent. solution of sodium cinnamate in a dose of 30 mimims, administered once or twice a week. According to his observation, a leucocytosis is caused, and the writer declares that if it is possible to make artificially a large increase in the most organized cells, it is probable that such an alteration will be made in the environments of cells which have reverted to the genetic type that an arrest in the reversion is possible and probable. Among the cases treated by this method have been two of cancer in the region of the pharynx and larynx. There was relief from pain and distressing symptoms in both. The discharges, also, were free from fetor which is so common in these cases. In a case of lymphatic recurrence, the gland rapidly disappeared after treatment, and the patient remains well two years at least after operation. In a case of breast tumor, the tumor disappeared altogether. Several cases of cancer of the bowel which have been treated, have improved strikingly. The writer believes that this drug inhibits the activity of the organisms which are connected with putrefactive changes. He has seen no patient die from sepsis when this method has been used. As far as he has observed, patients die from simple exhaustion. Early diagnosis is of the greatest importance.

An Investigation on the Regeneration of Nerves, with a View to the Surgical Treatment of Certain Paralyses.—Basil Kilvington gives the following summary of his paper: It is possible to functionate two opposing groups of muscles by a single nerve, which previously supplied one group only, or in other words, it is possible to innervate fairly completely muscles with a much smaller number of motor horn cells than usually bring about this effect. When the central end of one nerve is joined to the peripheral ends of two nerves there are many more fibers in the peripheral nerves than in the central nerves, so that the nerve fibers in the proximal trunk divide on going to the distal trunks. In some cases at least some of the branches one nerve fiber go to supply one set, and others the opposing set of muscles. This may prevent very delicate movement being restored. After this form of suturing the arrangement of the nerve fasciculi in the peripheral nerves is considerably altered. The experiments on this work are incomplete, as they have not been performed on the human subject, but the writer thinks that enough has been done to justify the clinical trial of the method. It would seem that some of the distressing cases of infantile paralysis for which so little can at present be done would be likely to be improved by such treatment. It may also be applicable to certain cases of injuries with loss of some of the length of nerves, tumors of nerves, and so on.

A Note on Mouth-Breathing as a Common Antecedent to Phthisis.—W. C. Rivers has examined a number of cases of tuberculosis and has found the percentage of mouth-breathers to be 19.4. Mouth-breathing was found to be due to various causes,—nasopharyngeal conditions, deflected septum, habit and uncertain causes, and projecting teeth. As a measure of general hygiene among the healthy, frequent change and speedy disinfection of handkerchiefs is advisable. Robust people who succumbed to tuberculosis did so more often at a later age, and under the influence of continued dust inhalation, than did the obviously weakly. This series was unselected, and it is worthy of notice that one-fifth were mouth-breathers.

Influenza.—T. Clifford Allbutt in speaking of the age of influenza, states that we know of it pretty definitely from the twelfth century onwards. And in perhaps every century since that time there has been a somewhat virulent outbreak. The epidemic of 1540 was very fatal. Since the epidemics in the thirties and forties of the last century, there have been epidemics mild in degree, excepting the one dating from 1889-90, which was much severer than the one in the forties. The disease seems to be endemic in Northern Central Asia, and from there it starts on occasional raids. The writer believes that the contagion, whatever it is, may be carried in clothes,—upon things as well as in human beings. This is probably true for a few days only. The writer has never seen a case without respiratory affection prove infectious. He believes that the disease is propagated in the sputum and spray from the respiratory tract. As to the bacteriology, there is no doubt as to the specific character of the Pfeiffer bacillus, and about the means of isolating, identifying, and cultivating it. But we are absolutely ignorant of its habits, whence it comes, where it is generated, and how it usually survives. The writer does not think that young children are very susceptible. Five or six months' immunization is usually conferred even on very susceptible people by an attack. As to the morbid anatomy, the writer believes that it is an inflammation of an erysipelatous type. In influenzal pneumonia the sputum is not rusty. Like phthisis, influenza may excavate the lungs. The heart is in more peril that it is in many other infectious fevers. Influenza attacks its victims with extreme suddenness. It is noted also that in convalescence the malaise often departs as suddenly as it came on. The temperature is not high nor prolonged. It is often below normal and may remain so for a time. Influenza is commonly divided into three types,—the respiratory, the nervous, and the gastro-intestinal. The writer adds a fourth, namely, the continuous form. For the disease keeps on in some cases with an indefinite febrile curve. Certain cases begin with violent neuralgic pains in the back and limbs, or head. Ear complications in children are a source of very grave anxiety. An interesting point in diagnosis is that the urine is not high-colored in this disease. Convalescence is extremely slow, and its duration is not in proportion to the attack. Neuritic and paralytic attacks sometimes occur. The veins are not very rarely attacked by phlebitis. Angina pectoris has been noted. In the case of a dilated heart, much nursing is necessary. These cases ultimately do well, for the intoxication is primarily rather of the nervous than of the muscular tissues. Chloroform should be avoided in these cases. One sequel not commonly mentioned is sweats which sometimes keep up for months after the attack, and are of a very profuse and trying kind. The writer concludes by emphasizing the fact that the patient should go to bed the moment that influenza is suspected, and stay there till the acute phase is well past. The diet should be one free from purin bodies, and much nitrogen, such as milk, custards, and the like, especially leaving out meat.

Preliminary Note Upon a Leucocytozoan of the Dog.—Charles A. Bentley discovered this parasite while he was

examining the blood of a number of dogs. These animals were of English breed, born in Assam. They showed no marked symptoms beyond a slight anemia and some little febrile disturbance. Nucleated red blood cells were present in small numbers in the blood. In dried blood films stained by Leishman's modifications of Romanowski's stain, one or more oval nucleated bodies were seen in many of the polymorphonuclear and transitional leucocytes. These bodies had a clear outline and their contents were more refractile than the protoplasm of the leucocytes. No signs of degeneration could be found in these bodies. There were marked changes in the contour and position of the nucleus of many of the leucocytes which were harboring these parasites. Fresh films showed the parasite as a rod-like refractile body lying in the protoplasm of the leucocyte, sometimes upon and at other times to one side of the neucleus. In one case a vermicule which had been freed from its enclosing capsule was seen for some time to make a side-to-side movement of one extremity, upon which appeared a markedly refractile spot. Leishman's stain gives the best results. The parasite is from 8 to 10 microns long, by 4 Mor 5 broad, with a nucleus of from 2 to 3 microns in diameter. It has been suggested that this parasite may belong to the hemogregarines. The writer declares that if this prove to be true, it will be the first hemogregarine reported as occurring in the blood of mammalian host, and the first to be found as a parasite of the leucocytes, in contradistinction to those already known to occur as parasites of the erythrocytes of cold-blooded animals.

Berliner klinische Wochenschrift, April 24, 1905.

Modern Methods in the Diagnosis of Surgical Affections of the Kidney.—Vogel reviews the various procedures by which different authors have attempted to solve the problem of determining the condition of the healthy kidney before nephrectomy. The methods of Achard, and of Voelcker and Joseph, who used subcutaneous injections of methylene blue and indigo carmine respectively, as a measure of the renal activity to be determined by watching the ureteral openings with the cystoscope, have proved to be unreliable, as well as the conclusions based on quantitative analyses of the various urinary constituents. Even the freezing point determinations of the blood on urine, as practised by Koranyi, are not wholly dependable, though this, as well as the phloridzin method of Casper and Richter, is of great value. The next step was in the development of methods of obtaining segregated urines of the two ureters, of which the most reliable is that by separate catheterization. Nitze has recently removed some of the objections to this procedure by devising a ureteral catheter with an inflatable balloon attached to it which is introduced into the ureter together with the catheter, and then serves to block the orifice completely and prevent all leakage. In this way it is necessary to catheterize only the suspected side, and there is, therefore, no risk of infecting the healthy kidney. The author sums up the present standpoint of renal diagnosis by saying that catheterization of the ureter is the most important aid in localizing disease and testing the function of the kidney. Having obtained separate urines in this way, the determination of the urea, cryoscopy and the phloridzin test, as well as cryoscopy of the blood must be carried out. All these methods are uncertain when taken singly, and a diagnosis should never be founded on any one of them alone. Only when the results of several coincide, is it safe to draw conclusions. In some cases they may all prove unsatisfactory, but it will then often be possibly by a careful microscopical, chemical, and bacteriological study of the separate urines, as well as by thoughtful analysis of all the conditions and of the clinical picture, to arrive at a correct diagnosis.

Münchener medizinische Wochenschrift, April 15, 1905.

A Danger of the Inverted Position in Operations on the Uterus.—Lauenstein enumerates several more or less serious sequelæ which have been attributed to the so-called inverted position which has developed from the original Trendelenburg position, and he describes a complication dependent on this source which he says has not yet been mentioned. A patient on whom an easy and uncomplicated supra-vaginal hysterectomy was done for fibroids, died twenty-four hours after operation of acute peritoneal sepsis. As the patient had been suffering from a profuse vaginal discharge, it is the opinion of the author that during the removal of the uterus some of this secretion, by the force of gravity or of aspiration, made its way into the abdominal cavity and gave rise to the acute infection. In this case the vagina had been sterlized in the usual way, but as it had not been supposed that a hysterectomy would be necessary, the vagina had not been packed with gauze. The author suggests that in order to prevent the possibility of such occurrences it be made the invariable rule to dry out the vagina before operation and to pack it with gauze in order to prevent any possible leakage of secretion.

Intussusception and a New Method of Operative Treatment.—K. Israel describes two cases of intussusception in children, with recovery, after an operation carried out on a new plan. The abdomen was incised over the intestinal mass and the colon sutured to the parietal peritoneum. The colon was then opened by a longitudinal incision and the intussusception drawn out until healthy gut was reached. At this point the intestine was cut through by degrees, and the two serous layers carefully united by suture, step by step, so as to avoid all contamination of the free peritoneal cavity. The line of sutured intestine was then pushed back along the gut so as to unsheath the invagination. The artificial anus was kept open a short time, as a precautionary measure, and then closed, both patients making good recoveries. The author warmly commends this method of extraperitoneal operation as much safer than the usual plan.

Radical Operation for Leg Ulcers.—Schneiderlin says that the multiplicity of remedies suggested for this condition is sufficient evidence of the inefficiency of all of them. He has had good results with a plan which depends on the following principle for this condition: The chief cutaneous veins of the skin, as a result of the inflammatory condition become overdistended and insufficient. The blood cannot be drained off properly in consequence of the insufficiency, and the ulcer remains in a state of chronic congestion. It is possible to relieve this state of affairs, and cause the ulcer to heal, by rest and elevation of the limb, but as soon as the treatment ceases the healed ulcer breaks down again. If it were possible to change the flow of venous blood into other healthy channels the chief cause of the ulcer would be removed. This can be done by completely blocking all the cutaneous veins and forcing the return stream to follow the deep veins. The operation consists in a circular incision carried completely around the thigh in its lower third, and extending down to the muscle and fascia. All the vessels are ligated on both sides and the incision closed by suture. The ulcer itself must also receive careful treatment, preferably by wet dressings of alumium acetate, which are changed three times daily. A number of cases are cited in which even long standing and rebellious ulcers were promptly cured by this method.

Deutsche medizinische Wochenschrift, April 27, 1905.

The Application of the Röntgen Rays in Warfare.—Schjerning says that the use of the modern small caliber projectile and the development of the Röntgen ray apparatus are the two most prominent features of modern military surgery. In all of the recent wars, in which nearly all races have been engaged, the Röntgen apparatus has been found so valuable that there is no difference of opinion as to its indispensability in military surgery. Operations and manipulations requiring such assistance are carried out both in the field and in the permanent hospitals. Although the extraction of bullets is no longer as important a part of the military surgeon's duty as formerly, it still happens frequently enough that foreign bodies must be removed from wounds, and in the treatment of bone injuries of all sorts the assistance of the rays is, of course, invaluable. It is, therefore, the duty of all military surgeons to be thoroughly conversant with *x*-ray technique, and the authorities must provide proper equipment. The essentials for such an outfit are that it shall be provided with means of generating its own current, and also of being arranged to make use of any available source of electricity, no matter what its nature; that it be extremely strong and simple, and that the entire outfit be comprised in a single wagon. Such an outfit has been devised, and is described and illustrated by the author. It contains a dynamo actuated by a gasoline engine, a coil with interrupter, rheostats for converting any commercial current, suitable sets of tubes, standards, etc., electric light clusters to be used in performing operations, and everything needed for the preparation of radiographic negatives and positives. Tests as to the durability and serviceability under adverse circumstances of this outfit have shown that it is thoroughly practical and capable of answering all demands upon it.

Experiences in One Thousand Appendix Operations.—Kümmell says that the increased frequency of appendicitis in modern times is both apparent and real, being partly due to more accurate diagnosis by the profession, and the education of the public, and partly to an actually greater prevalence of the disease. Causes of the latter are the changed conditions of life, especially the greater consumption of meat, and the wider dissemination of the infectious diseases, particularly of influenza. He also considers that heredity plays a part in the production of some cases, and he cites instances in which numerous, partly non-related, members of the same household have been attacked. Of 1,000 cases treated by the author, 695 were operated in the interval, with a mortality of ½ per cent.; 49 in the acute stage, with a mortality of 6 per cent.; 178 cases with abscess forma-

tion, with a mortality of 10 per cent; and 82 cases of diffused peritonitis, with 89 per cent mortality. In regard to the indications for operation, the author says that every patient who has once had a single pronounced attack of appendicitis should have the appendix removed, if possible during the interval. Every case should be operated at once, the earlier the better. These two propositions are now pretty universally accepted, but there is still difference of opinion as to what to do with cases that are not seen until about forty-eight hours after the beginning of the attack. In general, unless immediate intervention is urgent, expectant treatment with opium, ice, etc., is advisable, cathartics being strictly avoided. Abscesses should be opened as soon as possible, but the removal of the appendix is better deferred to a secondary operation.

The Röntgen Rays in Dentistry.—Miller reproduces a number of radiographs to show the value of the *x*-rays in the diagnosis of various dental conditions. Among these are deep alvelor abscesses, or pus collections at the root tips, caries of the alveolus, thickening of the root through deposits of cementum, absorption of the roots, in the determination of the presence or absence of retained teeth, in ascertaining the position of the roots of teeth that are to be regulated, the presence of new growths of the pulpa, in the detection of fragments of needles or instruments broken in the course of operative work, or of buried roots, cysts, fractures, of the jaw, etc. All of these applications may be of the greatest utility and furnish information that is obtainable in no other way.

French and Italian Journals.

Experimental Researches in Putrid Pleurisy.—Guillemot, Hallé, and Rist have made on several occasions inoculations [illegible] rabbit's ear. They have also made inoculations into arteries. By these experiments they have proved that multiple and varied lesions, putrid and gangrenous, can be produced through the agency of the blood. Intravenous inoculation often gives rise to pulmonary infarcts. In rare instances the lesions go on to gangrenous transformation, but generally the animal dies too soon for this change. In the cases of pulmonary infarcts, obliteration of the arteries has often been noted. The vessel is then filled with a putrid mass. In other cases, the lung has many small foci of the size of a grain of wheat and of a small pea. These foci are white in color and are surrounded by a hemorrhagic zone. These lesions resemble those of embolic gangrene of the lung. Vegetative endocarditis can be produced by this same method. In all of the cases it has been possible to recover the anerobic microorganisms which have been inoculated. In one case, small, multiple abscesses of the liver were produced, a lesion very rare and difficult to obtain even with the septic microorganisms of the anerobic series. Suppurative arthritis was observed in these experiments in one or two cases.—*Revue Française de Médecine et de Chirurgie,* May 1, 1905.

Phlegmatia Alba Dolens of Ganglionic Origin.—Courtois-Suffit and Beaufumé relate the history of a patient who in the course of an attack of typhoid fever, which was not very severe, suffered from the complication of phlegmatia alba dolens. The phlegmatia occurred in the right leg during convalescence. It presented the usual classical picture, with the exception of beginning in an abnormal manner. The first indication was the development of a voluminous subinguinal adenitis. For three days, besides the slight febrile manifestation, this was the only clinical symptom of the infection. This affection was easily diagnosed, but its true significance was not recognized until after the symptoms of phlebitis appeared. In this case the adenitis was the clear index of a deep venous infection, which had affected the lymphatic system before the venous obliteration was established. No explanation of this condition is attempted, but the clinical fact remains undisputed. —*Revue Française de Médecine et de Chirurgie,* May 1, 1905.

Experimental Aortic Atheroma.—A. Pic and S. Bonnamour refer to certain experiments in which atheromatous lesions of the aorta have been caused by repeated intravenous injections of small doses of adrenalin in rabbits. In their own work, they met with absolutely negative results in the case of two rabbits, although the experiments extended over a period of three months. But the animals were young and weighed respectively, 1 kgr. 220, and 1 kgr. 300. The first essential factor in this work is that the animal experimented on shall weigh over 2 kilogrammes. The injection of the watery extract of the suprarenal body has the same effect as that of adrenalin. The adrenalin acts more surely and more rapidly when the resistance of the animal is lessened as in the case of tuberculosis or lactation. These investigators have also experimented with trinitrin, but this had no effect on the aorta.—*Bulletin de la Société de Biologie,* February 4, 1905.

Three Cases of Exophthalmic Goitre Treated With the Blood and Serum of Thyroidectomized Sheep.—P. Sainton and B. Pisanté report these three cases. The first patient was a woman 35 years of age, who had been ill for a year and a half. She had been treated with various drugs, among which were thymus extract and thyroid capsules, but with no effect. The symptoms of the disease were much accentuated in this case. There were present arhythmia of the heart, edema of the limbs and progressive weakness. A spoonful of the blood of a thyroidectomized sheep diluted with glycerine and put into coffee, was given to the patient. Improvement followed. The results of the administration of serum were still more marked. The second patient was a man 31 years of age. Improvement followed the administration of the sheep's blood. The treatment was stopped and a relapse was the result. The treatment was renewed with the same excellent results. The third patient, a woman of 51 years, was treated by injections of the blood. She had been suffering with goitre for ten years, but this treatment was rewarded by progressive improvement.—*Revue Neurologique,* December 1, 1905.

Feeding Subcutaneously.—Giuseppe Crisafulli details his experiments on animals, as well as human beings, as to the absorption of food materials when injected under the skin, and their effect on the system. He wished especially to clear up the point whether alimentary substances injected under the skin are useful, or whether they are injurious, and which of them have the greatest nutritive value. He experimented on cats, dogs, rabbits and man. He injected butter, oil, isotonic physiological serum solution, in one series; glucose, and peptone in another series; [illegible]r and salt solution in a third and fourth. His conclusions are that none of the solutions injected had any value in maintaining life longer than in an animal which received no nourishment at all. As a result of these experi[illegible]ts, the author does not advise the use of food substances [illegible]aneously.—*Giornale della Associazione Neapolitana di Medici e Naturalisti,* No. 3-4, 1905.

Second Attack of Smallpox.—Alfonso Montefusco details the case of a baby, who had recovered from a mild attack of smallpox. Six days after its discharge from the [illegible]ital it was attacked by smallpox in a virulent form, to which it succumbed. The author had previously observed a similar case in an adult, who was treated for an undoubted attack of smallpox, and a few days after his [illegible]harge returned to the hospital for treatment for another eruption, having all the characteristics of a true smallpox. Several similar cases have been recorded in literature, for instance, that of Louis XV., who had smallpox at twenty, but died of it at 64. The author also tells of a boy of 14, vaccinated in the previous summer successfully, who had an undoubted attack of smallpox. A second attack of measles is quite common, while in scarlet fever and smallpox it is rare. An immunity is conferred by one attack of the disease, but this may not be permanent, just as the period of immunity conferred by vaccination varies much, and finally passes away. The immunity in smallpox is not always permanent. The author believes that the microorganism of smallpox remains latent in the system, in organs and tissues, and responds to a slight exciting cause, which determines a second attack.—*Giornale Internazionale delle Scienze Mediche,* April 15, 1905.

Etiology and Pathology of Hepatic Cirrhosis in Infants.—L. M. Spilverini draws our attention to the common belief that hepatic cirrhosis in infants is comparatively rare, much more so than in adults. His observation has led him to believe that such cases are much more common than is generally believed. The liver of an infant has a different physiological attitude from that of an adult, and the functional reactions in the presence of morbific agents have different characters. If the forms of hepatic cirrhosis are difficult of diagnosis during life the author thinks it desirable to publish such cases. The principal causes of the disease in infants are (1) Infective syphilis, tuberculosis, malaria, biliary infection. (2) Toxic—alcohol, dyspepsia, splenomegally. (3) Mechanical—circulatory. The most frequent variety is of syphilitic origin. The malarial form is uncommon, as is that of circulatory origin. It has been supposed that the alcoholic form was rare, on account of the tender age of the child. There is reason to believe that this is not the case, since it is found that among the poorer Italians, especially of the Roman Campagna, it is the custom to give children wine as a daily food, and they even drink it as a beverage at night when thirsty. The author describes two such cases, one of which recovered slowly when the alcohol was stopped, while the other, a baby of 18 months, died. The dyspeptic form is also rare. The chief reason of this is the resistance of the child's system to the poisons from the intestine. A third case was one of hypertrophic cirrhosis, with chronic icterus. Onother occurred in a child afflicted with a very extensive eczema, which the author believes to have been the cause of a toxo-infective cirrhosis. The liver had a smooth surface, regular border, uniform increase in size of both lobes, with a marked ascites, and no icterus.—*Rivista di Clinica Pediatrica,* April, 1905.

Book Reviews.

Résurrection du Cœur; La Vie du Cœur Isolé; Le Massage du Cœur. Par le Dr. Maurice D'Halluin, Chargé des Travaux pratiques de Physiologie á la Faculté Libre de Médecine, Ancien Préparateur de Physique biologique, Externe des Hôpitaux, Lauréat de la Faculté Libre de Médecine. Avec 22 Dessins et 6 Planches hors texte. Paris: Vigot Frères; Lille: Vve. A. Masson, 1904.

In this book the author gives us the results of his experiments and researches on the important topics mentioned in the title. He first discusses the various methods that have been employed in isolating the heart; then he passes in review the serums that have been used at different times to produce an artificial circulation. Next, the author's attempts at reanimation are detailed. His experiments were conducted on dogs and still-born infants; in the case of the latter he was particularly successful, being able to record contraction of the ventricles after a lapse of twenty-four hours, and of the auricles after so long a time as forty-two hours. The second part deals with the possibility of resuscitating a person who has ceased to breathe; and the last half of the volume treats of the massage of the heart (including methods, results, and reasons why it has not always been successful in the past). The book is instructive and entertaining, and those interested in the subject will enjoy reading the volume in the original.

Practical Manual of Diseases of Women and Uterine Therapeutics, for Students and Practitioners. By H. Macnaughton-Jones, M.D., M.Ch., Master of Obstetrics (honoris causa), Royal University of Ireland; Fellow of the Royal Colleges of Surgeons of Ireland and Edinburgh; formerly University Professor of Midwifery and Diseases of Women and Children in the Queen's University, and Examiner in Midwifery and Diseases of Women and Children in the Royal University of Ireland; ex-President of the British Gynecological Society; Corresponding Member of the Gynecological Society of Munich. Ninth Edition. New York: William Wood & Co., 1905.

The first edition of this book was issued in 1884, and contained 410 small pages. This ninth edition appears as the book "comes of age," and contains more than 1,000 large pages; indeed, the various enlargements and improvements rendered necessary by the great strides made by Gynecology during this period, have resulted in making the volume almost too bulky to be easily handled. Among the topics that are responsible for this growth may be mentioned: Asepsis and antisepsis; ovarian and uterine tumors and their treatment; tubal pregnancy; deciduoma malignum; affections of the bladder, ureters, kidneys, and rectum; electrotherapeutics; ovulation and menstruation; internal secretion of the ovary; value of rectal exploration in female children; the ophthalmoscope in diagnosis; curettage; ventrofixation; hysterectomy. Besides these, many histories of cases have been introduced and the illustrations have been enlarged, and increased in number. We think that the book might have been kept within smaller limits if the sections on the affections of the bladder, ureters, kidneys, and rectum had been omitted. These subjects hardly belong to gynecology proper, and although the chapters dealing with them are quite up to the high level of the rest of the volume and add very considerably to the value of the book, they also add to its bulk. From the first this book has held an enviable place among text-books on gynecology, and this new edition will no doubt prove as popular as former editions have been. Nine editions in twenty years is evidence enough of merit on the part of the book and of appreciation on the part of the profession.

The Urine and Feces in Diagnosis. By Otto Hensel, Ph.G., M.D., Bacteriologist to the German Hospital, and Richard Weil, A.M., M.D., Pathologist to the German Hospital, New York, in Collaboration with Smith Ely Jelliffe, M.D., Ph.D., Instructor in Pharmacology and Therapeutics, Columbia University, etc. With 116 engravings and 10 colored plates. Philadelphia and New York: Lea Brothers and Company, 1905.

This book is a laboratory guide to the examination of the urine and feces, and as such is as complete and up to date as any that have recently appeared. It is, however, distinctly a guide for the laboratory worker, the student, and the physician with a bent toward laboratory work, and does not emphasize the clinical relations of its subject to the extent which might be desirable. The section on the urine (by Hensel) has been brought up to the very latest time: for example, the pancreatic reaction (1904) is spoken of. The subject of urinary diagnosis is considered in a table and scarcely one page of text, while the significance of individual elements is too scantily treated in many instances—an evidence of the neglect of the clinical side of the subject, already spoken of.

The section on the feces (by Weil) presents a detailed consideration of the methods of examination. The normal and abnormal constituents of fecal matter, and the bacterial flora of the intestinal contents. This part of the book is of special value to the laboratory worker who wishes to have all the latest researches on this subject accessible in a condensed form. The work of Ford, Miguela, etc., has been freely drawn upon, and the bacteriological section is most complete. Ten pages are devoted to the characters of feces in disease, and the diagnostic side of feces is rather more freely considered throughout this section than is the clinical side of uranalysis in the first part of the book.

The authors have done their work accurately and thoroughly, and in many ways the book is an excellent one.

The Diseases of Society (The Vice and Crime Problem). By G. Frank Lydston, M.D., Professor of Genito-urinary Surgery, State University of Illinois, Professor of Criminal Anthropology, Chicago Kent College of Law, Surgeon to St. Mary's and Samaritan Hospitals, etc. Philadelphia: J. B. Lippincott Co., 1905.

The author's views on the vice and crime problem expressed in this work are evidently based on long and close observation of the social system and its diseases. In earlier chapters are given his reasons why we have been unable in this country to diminish this volume of defectives. These are in brief ignoring the adverse social conditions directly responsible for members of this class, society permits them to breed, and contents itself with punishing them after they have become a menace. He emphatically condemns this system, and in succeeding chapters, notably on the therapeutics of social diseases, are presented the remedial measures which he deems expedient and effectual. With a very far-seeing eye, he predicts the final abolishment of all punitive, and the substitution therefor of reformatory institutions and principles. Perhaps equally far-seeing is he in his prediction that society will eventually avail itself of the right to impose a legal restraint on the marriage of the defective class, and of sterilization or asexualization as effective substitutes.

A Utopian dream, possibly, and yet one must feel the necessity of such measures with the gallery of outcasts in mind that adorns these pages. Vivid descriptive and photographic characterizations these are, of the type that society permits to propagate, while ineffectually struggling with results.

Ailments of Women and Girls. By Florence Stacpoole. Certified by the London Obstetrical Society, Lecturer for the National Health Society and for the Councils of Technical Education; author of "Advice to Women on the Care of Their Health, Before, During, and After Confinement," "Our Sick, and How to Take Care of Them," etc., etc. Bristol: John Wright & Co.; London: Simpkin, Marshall, Hamilton, Kent & Co., Ltd., 1904.

Although this is a small manual of only 238 pages, it teems from cover to cover with helpful advice. The writer believes that "suffering is not woman's necessary lot." The various ailments common to girls and women during the different epochs of their lives are skilfully discussed. The style is clear, simple, and interesting. After the first chapter, which describes the uterus and its surroundings, the author considers the broad subject of Menstruation, with its many and varied complications. Warning is given as to the danger incurred by women who attempt to treat themselves in any trouble at all serious. Still, many a life could be saved if women had enough knowledge to act in emergencies before a physician can reach the patient. Simple remedies are suggested for various disordered conditions. Some of the subjects treated are: Cancer of the Uterus, Displacements and Inflammation of the Uterus, Inflammatory Disorders of the Vagina and Vulva, Care of Delicate Girls, Anemia, Chlorosis, and Indigestion, Backache, Urinary Troubles, Constipation, Piles, Headaches, Hysteria, and Neuralgia. Many pertinent quotations from authorities on these subjects are scattered throughout the text. The volume is a most valuable one not only for women in the home, but also for physicians. There is an excellent index.

Die Vergiftungen. Von Dr. Med. O. V. Boltenstern, Prakt. Arzt., Staatsärtzlich approbirt. Leipsic: C. G. Neumann, 1902.

This small handbook of poison-lore is designed especially as a practical guide for the physician in dealing with cases of acute and chronic poisoning. No attempt is made to cover the whole field of toxicology, but the symptoms and the treatment of poisoning with various substances are given in sufficient detail for practical purposes. A good index is provided, and the book appears in the convenient form common to the other volumes of the series known as "Medicinische Bibliothek für praktische Aertzte."

Society Reports.

ASSOCIATION OF AMERICAN PHYSICIANS.

Twenty-first Annual Meeting Held in Washington, D. C., May 16 and 17, 1905.

(Special Report to THE MEDICAL RECORD.)

The President's Address.—Dr. E. L. TRUDEAU of Saranac Lake, delivered the address reviewing briefly the Association's work since he became a member in 1886, and stating that it had more than fulfilled its destiny along certain lines. He referred briefly to the loss of three members during the past year, one by death and two others by removal to England.

A Study of the Fear of Cats and the Power to Recognize Their Presence Unseen and Unheard.—Dr. S. WEIR MITCHELL of Philadelphia presented this communication, reporting in detail two instances in which people were able to recognize a cat in the room unseen and unheard. Dr. Mitchell said he had made inquiries regarding this recognition of cats, dogs, and sheep by persons when the animals were unseen and unheard, and had received 159 replies from different parts of the world and from many well-known people. About one-third of the replies were valueless for several reasons. In some cases the odor of the animal announced its presence. In others the olfactory organs were the parts through which the fear, terror or disgust was suggested, but without the recognition of any sense of odor as the cause. Besides the fear, terror or disgust excited by the presence of these animals, there were many other symptoms [illegible] upon the removal of the animal. The symptoms in most cases appeared during early childhood, but there seemed to be a remarkable increase in the manifestations of the peculiar phenomena at the time of puberty. In one-quarter of the cases the condition was spoken of as a family peculiarity; in one family there were five instances, in another seven, although single cases in a family was the rule. Sex appeared to have no influence. It had been claimed that Washington was disturbed by the presence of cats, although there could be found nothing in the way of distinct evidence to prove this assertion. After a very careful examination of the replies received, he reached the conclusion that 31 per cent. gave distinct evidence of being able to tell the presence of cats unseen and unheard. The emanations from cats he said might produce emotional disturbances without the olfactory nerves recognizing odors.

Intrapleural Lipoma: Pericardial Exploration.—Dr. R. H. FITZ of Boston said that intrapleural lipomata might grow from the subperitoneal subpleural and mediastinal fat tissue, and project into the pleural cavity from the diaphragm, costal wall or from the mediastinum. The diaphragmatic lipoma was a rare anatomical curiosity, only two cases having been reported, and had had no clinical significance. The costal subpleural lipoma might penetrate the wall of the chest and appear as an external tumor connected by a stalk with the internal growth. Three such tumors had been operated upon with two deaths. The mediastinal lipoma might penetrate also the thoracic wall and grow upon the surface of the chest. Three cases had been reported and were operated upon with fatal results in all. Dr. Fitz reported a unique case occurring in a patient 24 years old with a history of a pneumonia with supposedly delayed resolution. It turned out to be a case of pedunculated lipoma, intrapleural, of mediastinal origin. Its significance in the differential diagnosis of pericardial and pleural effusion was suggested and its diagnosis considered possible. Its presence was explanatory of the failure to obtain pus in purulent pericarditis. He said the xiphocostal route was to be preferred in pericardial exploration by paracentesis or incision and in the establishment of drainage. In the case reported the lipoma was the size of an infant's head. The diagnosis should be made by puncturing the growth and examining for the drop of fat under the microscope.

Dr. JAMES EWING of New York reported an instance of such a tumor consisting of five lobules about the size of a goose-egg each; this was found in the dissecting room. Each was connected to others by pedicles. It surrounded the aorta as well as encircled the diaphragm.

Dr. WILLIAM OSLER of Baltimore agreed that it was better to enter at the xiphocostal entrance in puncturing for pericardial effusions, and said that fifteen or sixteen years ago he had made a series of observations in the Philadelphia Hospital with reference to this point, whether there was any danger of perforating the liver, etc. In every instance he found that you could readily puncture into the pericardial sac, and he had done it often with perfect safety in cases of pericardial effusions. He referred to one case in particular that had been tapped in several places on several occasions and only a very small amount of fluid had been obtained each time; when the xiphocostal route was chosen by far the largest amount was obtained. There was undoubtedly an exudate which depressed the liver and diaphragm as well, and kept it from being endangered. He called attention to the frequency with which patients died with large pericardial exudates, and recently, in going over the pneumonia records, he said there were at least four or five whose lives might have been saved by operation. He advocated the more frequent use of the small hypodermic needle; if one should puncture the heart near the apex no harm would result.

Dr. GEORGE L. PEABODY of New York spoke of the different types of pneumonia cases encountered each year; during the past winter the fibrinous exudate could not have been detected by the use of any small hypodermic needle. He believed it better to wait until there were evidences of impairment of cardiac function by the exudate and then to remove the exudate.

Dr. FORCHHEIMER of Cincinnati, Dr. WM. P. NORTHRUP of New York and Dr. ROACH of Boston also discussed the paper.

Rhythmic Lateral Displacement of the Heart as a Sign of Unilateral Pleural Exudate.—Dr. CHAS. L. GREENE of St. Paul read this paper. In 1902 he had called attention to a hitherto unobserved sign of unilateral pleuritic exudate, consisting of a rhythmic lateral displacement of the heart, synchronous with respiration and extended observation during the past three years confirmed the original observation and showed that the sign was of value in differential diagnosis. A number of cases were quoted in support of the foregoing statement, a large number representing other conditions having failed to show rhythmic lateral displacement. It was absent in subdiaphragmatic abscess, malignant disease of the lung and pleura and in pneumothorax. The sign was best observed by the fluoroscope or by auscultatory percussion. The degree of effusion markedly influenced the movement; trifling effusion failed to show it; massive effusion was accompanied by a minimum of rhythmic displacement. The sign was sometimes obtained by inspection, but such observation was subject to error. It was more readily recognized in right than in left-sided effusion. Deep respiration was necessary and might require the exhibition of morphine for the relief of the attending pain. He doubted the statement, generally accepted, that in certain cases of effusions the diaphragm was rendered immovable or bulged into the abdominal cavity, no such a condition having been observed. He also took issue with the statement that the extent of cardiac displacement in liquid effusions could be accurately determined without the use of the fluoroscope, auscultatory percussion in cases of displacement to the left and simple percussion having yielded outlines corresponding accurately to fluoroscopic findings. In a résumé of the probable causes of rhythmic lateral displacement he took the ground that in the presence of unilateral exudates of considerable quantity such movement was inevitable on the basis of purely physical causes, the anatomical structure and physiological

mechanism of the thorax and its contained organs. His conclusions were (1) A rhythmic lateral movement of the heart occurred in unilateral liquid pleural effusions; (2) such movement was most marked in medium-sized effusions; (3) the heart approached the affected side in inspiration and moved outward in expiration; (4) the extent of movement was variable, but often amounted to two inches; (5) that it might be measured by fluoroscopic examination, auscultatory percussion, or in the case of right-sided effusions by simple, deep percussion of the free cardiac border, or in some instances by mere inspection of the chest; (6) deep breathing and especially forced expiration were essential to the success of the maneuver and, to obtain this, morphine must sometimes be administered; (7) marked rhythmic lateral movement had not been found in pneumonia, tuberculous infiltrations of the lungs, malignant disease of the pleura or lung, or in subdiaphragmic abscess.

Gonorrheal Septicemia and Endocarditis.—Dr. W. S. Thayer of Baltimore said that the frequency of valvular endocarditis in septicemia was not well known and that in many instances it was of specific origin. He took up a consideration of several cases of gonorrheal septicemia and ulcerative endocarditis that had occurred at the Johns Hopkins Hospital, and also one instance of general gonorrheal septicemia associated with arthritis without other apparent complications. In this case there was a continued fever, simulating in some respects typhoid fever of over two months' duration where there was complete recovery. Gonococci were obtained in pure culture from the circulating blood. This patient recovered and without any apparent bad results, and it was now some five or six months after the infection. He referred to a series of 10 cases, 2 being but recently seen, of gonorrheal endocarditis; in 6 the gonococci were positively identified, four during life from blood culture, and two alone at autopsy. In three instances with a mixed infection there was also a general gonorrheal invasion. In five cases there was an endocarditis preceded by a more or less acute gonorrhea without other apparent causes. He wished to emphasize the fact that urethritis was not infrequently followed by endocarditis.

Dr. William Osler of Baltimore said we should not forget those cases of acute pulmonary septicemia in which there was an overwhelming toxic cause. One such a case was reported by Howard which was first regarded as one of typhoid and the patient died within one week; there was found a gonorrheal septicemia, endocarditis, and a slight pocket of pus was found in one lobe of the lung.

Fever in Chronic Endocarditis.—Dr. J. S. Thatcher of New York said that he had been struck by the great number of cases of endocarditis in which there was a considerable amount of fever without any explanation for that fever. He gave an analysis of 1,001 cases observed at the Presbyterian Hospital. After deducting those cases which he did not believe should be included, there remained 900 cases, and these he divided into several groups according to the temperature range. In one group in which the temperature never went above 100 degrees he was surprised to find 316 cases, and two-thirds of the cases were above 100. In 585 cases the temperature at times was above 100. The febrile cases number over 131, in which there were articular symptoms. There were 23 cases with distinct petechial or hemorrhagic eruptions. Taking out all those cases with signs of certain complications there was left but 291 cases in which there was fever above 100, and in which there was no apparent explanation for the fever, unless there was a bacterial explanation. Of the 23 eruptive cases 18 died. The studies at autopsies in these cases showed that the petechia were not necessarily associated with ulcerative vegetations. In those cases in which frank signs of complications which might have caused a considerable elevation of the temperature there were 207 cases with 254 complications. The most frequent complications were lobar pneumonia, pericarditis, etc. Among the 291 cases in which there was more or less fever, but in which there were no distinct evidences of complications to correspond to that fever, about 45 per cent. were due to the presence of chronic endocarditis. In 16 cases where the fever went above 103, there were no faint indications of unimportant complications, such as pain on one side of the chest. It was peculiar to note that the afebrile cases gave a larger mortality than the febrile; the afebrile cases gave a mortality of 19 per cent., while the febrile gave one only of 7 per cent. The frank cases with complications showed a mortality of 35 per cent. One of the most striking points was the large number of cases encountered with fever and without any possible explanation for that fever.

Dr. A. Jacobi of New York said that often we were apt to make a diagnosis of endocarditis when there was a systolic murmur, when there was a myocarditis present. He had had such cases under observation year after year; now and then they turned up with a systolic murmur (mitral). Then they would get better and remain so for months after treatment by rest, etc. The murmur would be brought out by the slightest exertion.

Dr. James Tyson of Philadelphia spoke of the relation between pericarditis and these petechial eruptions.

Dr. Victor Vaughan of Ann Arbor said that the toxic effect upon the temperature depended upon the kind of germ and upon the rapidity with which the poison of that germ was set free. We all knew that the clinical differentiation between tonsilitis, for instance, and diphtheria rested with the degree of temperature; if it were 103° or higher it was in all probability a case of tonsilitis; whereas if below 100° it was diphtheria.

Dr. William Osler of Baltimore presented a remarkable chart showing the temperature curve in a case of chronic endocarditis. In certain cases of endocarditis with a fatal outlook recovery would take place. He had one patient under observation about fourteen years who had had several extremely severe attacks of fever in connection with a mitral endocarditis and who recovered from each attack.

Dr. Francis P. Kinnicutt of New York had seen several cases such as described by Dr. Osler, one case lasting five and another lasting seven months, and to-day, although the murmur persisted, they were apparently in excellent health.

A Case of Hemophilia with Special Reference to Joint Disease.—Dr. Francis Kinnicutt of New York called attention to a patient, 16 years of age, whose family history was negative so far as any hemorrhagic diathesis was concerned. From birth, the skin was thin and of delicate texture. When five months old, a small swelling in the leg appeared, which was quite discolored. A blackish lump appeared on the chest, which persisted for many weeks. When two years old, the patient had nose-bleed, which was difficult to control, and until the age of five years he was never free from hemorrhagic spots appearing on different parts of the body. At the age of five, he began to have attacks of what appeared to be inflammatory rheumatism. A nose-bleed occurred when eight years old, which was controlled only after forty-eight hours' efforts. A blow on the thigh produced a lump, a large extravasation. The year following bleeding from the nostril occurred, lasting for several weeks. There occurred what was supposed to be an acute attack of rheumatism of the left hand. Dr. Kinnicut saw the patient in 1897, and the patient died seven years later. The often recurring joint symptoms were supposed to be of rheumatic origin. The temperature was but moderately elevated. Various joints were involved, and at intervals that varied greatly. Attacks of hematuria occurred. There were no very severe arthritic attacks until in 1902, when a large interstitial hemorrhage occurred in the extremities. From 1902 until 1904 he had attacks of severe hematuria and effusions into the left elbow joint, etc. In all the attacks the pain was present and the temperature went as high as 103.5°. In February, 1904, the patient complained of acute pain in the lower part of the abdomen and became blanched; the whole

abdomen was distended and rigid, with tenderness and muscular rigidity present. The temperature was 101° and pulse 120, but during the following week the symptoms became grave, the temperature ranging between 100° and 103°, but finally absorption gradually occurred. In July, 1904, there appeared acute symptoms and abdominal pain. No blood passed by way of the bowels. A fatal issue occurred twenty-four hours after the occurrence of the first symptoms.

Clinical Notes on Opium in Myocarditis.—Dr. JOHN H. MUSSER of Philadelphia spoke of the beneficial effects which seemed to have occurred in many typical instances of myocarditis. In senile weak heart, there was no doubt but that the continued use of opium was of advantage. It was also of great value in chronic myocarditis, in order to prevent the occurrence of insults to the cardiovascular system. Opium was not contraindicated in chronic myocarditis attended by melancholic symptoms. In case of myocarditis or endocarditis more satisfaction was to be had by the continued use of opium than from the use of any of the so-called cardiac drugs.

Dr. M. H. FUSSELL of Philadelphia referred to an instance where, after the subsidence of an acute pneumonia, an extremely weak heart occurred, in which the use of morphine was followed by the happiest results and appeared really to have saved the patient's life.

Dr. BEVERLEY ROBINSON of New York thought that all would agree that in most cases of so-called heart failure nothing stimulated the heart more than opium.

Dr. A. JACOBI of New York said that opium was just as useful as strychnine was harmful, and no remedy had given worse results and done more haim in the average case of myocarditis than strychnine.

Some Phases of the Neurotic Heart.—Dr. BEVERLEY ROBINSON of New York read this paper, in which he stated that nervous disorders of the heart were not well understood, and he presented and emphasized certain facts. Apparent or evident slight enlargement of the heart, with or without dilation, was occasioned by or preceded directly from cardiac neuroses. There was also a condition of secondary anemia, as shown by the microscopical examination of the blood, which resisted all kinds of treatment, and also an absolute or relative uselessness of digitalis unless the heart muscle itself was involved. There was also an impaired nutrition with an accompanying slight cardiac dilation, which subsequently remained stationary and functionally compensated.

Report of a Case of Pneumococcus Sepsis.—Dr. J. S. THATCHER of New York reported a case of acute lobar pneumonia, which was followed by empyema and an intense and rapidly progressing general infection by the pneumococcus with malignant endocarditis and meningitis.

A Report of Six Cases of Perforation in Typhoid Fever in Children.—Dr. J. P. CROZER GRIFFITH of Philadelphia made this report. The first case was a girl, twelve years old; on the twenty-third day of a severe attack she developed severe abdominal pain without vomiting or collapse or any fall of temperature, and it was not until the day following that she really appeared very ill. Twenty-four hours after vomiting began, and there was a slight abdominal pain, distension of the abdomen began to increase and the diagnosis of perforation was made. No operation was possible. The second case was a boy, eleven years old, who suffered from pleurisy, a complication of typhoid fever of mild type. He ate icecream one day, and as a result abdominal pain occurred, and vomiting. There was also a slight rise of temperature. On the day following the patient became worse and was supposed to have an attack of severe indigestion from indiscretion in diet. It was not until two days following that it was discovered that he had suffered a perforation, and operation then could not be performed. The third case presented symptoms of perforation, with a sudden drop of temperature from 102 to 97 and severe abdominal pain. Forty hours later operation was performed, but it was unavailing. The fourth case was a boy eight years old, and the perforation apparently occurred in the third week of the disease. Vomiting was the first symptom, and there was no fall of temperature and no collapse or abdominal pain. There was but moderate abdominal distension. Operation was asked for and refused. The fifth case was a girl of four years, who passed from a mild attack into convalescence, having had no fever for a week. The perforation appeared to have occurred about the end of the third week, when she complained of some stomach ache. There was no elevation of temperature and she did not appear to be at all ill. The child was sitting up in bed, and then the temperature gradually rose, with occasional vomiting, but without abdominal symptoms. The next day she died, and without abdominal distension or pain. The sixth case was a girl of six years, who was presumably in the second week of the disease. The history of this case was very vague. She had an excellent pulse and but slight tenderness, but only on firm pressure. She was operated upon, but she, too, died on the seventh day after. Dr. Griffith made reference to the variance in published statements regarding the frequency of perforation in typhoid fever in children, the general trend of opinion being that it was rarely seen. More recent observations tend to show that probably it occurred more often than had been supposed. Basing his remarks on the condition seen in most of these six cases, he concluded that the accident was more difficult to recognize than in adult life. There was often a less degree of constitutional impression. Abdominal pain and tenderness might be absent or trivial, and in many instances the statement of the child was less to be relied upon than in later life. Vomiting was so frequently a symptom in different diseases of childhood that its occurrence in perforation was of little import.

Dr. A. JACOBI of New York said that cases of perforation were often seen without even diarrhea preceding, not even occurring during the entire course of the disease. Diagnosis was almost impossible in many cases.

Dr. GEORGE L. PEABODY of New York said that we should not look for diarrhea as one of the symptoms of perforation, and it was rather the rule to have perforation without diarrhea.

Hematemesis from Gastric Ulcer; Notes on Over Two Hundred Cases.—Dr. W. GILMAN THOMPSON of New York presented data based upon records of the Presbyterian and Bellevue Hospitals, and the conclusions arrived at were that operation should be undertaken more often than now. He admitted the great difficulty of an accurate diagnosis of the condition of the stomach. The examination of gastric contents, especially when done but once, was of no value whatever in the diagnosis of these cases. Some chronic cases began with large hemorrhage and hematemesis could not be used as a basis upon which to classify these cases clinically. The surgical records in the treatment of gastric ulcer were now very encouraging, and Moynihan had presented 123 gastrotomies for gastric ulcer and only lost two cases as the result of operation. It was very desirable to have earlier operative interference in these cases.

Dr. FRANCIS P. KINNICUTT of New York said that it should be borne in mind how frequently perforation and hematemesis occurred, and yet the point of ulceration was never discovered; the most careful search for the ulcer was needed in many cases, and he referred to a case that had been operated upon by Dr. Weir and Dr. Abbe with a fatal result following; at autopsy, the most careful search was demanded to discover the gastric lesion. He said that frequently death seemed to be imminent when the hemorrhage would suddenly cease and the patient get along all right without further trouble.

Dr. J. SOLIS COHEN of Philadelphia spoke of an operation that had been advised at the Philadelphia Hospital. The patient was a man well advanced in years, a carpenter by trade, who had a profuse gastric hemorrhage without pain or other symptoms of any definite kind. It was de-

cided that he was too weak to submit to operation, and the patient then got better; then it was decided that the necessity for operation, under the circumstances, had passed. The man, however, died, and the autopsy showed thirty or forty ulcers, twenty-nine or thirty-nine of which had healed. Death was the result of the last large ulceration. Here there were multiple ulcerations, which had occurred without giving rise to symptoms. He reported another case, to show the vagaries of gastric ulcer.

Dr. Sippy of Chicago asked when one was permitted to operate after perforation. One should hesitate to operate when the hemoglobin had fallen under 40 per cent.

Dr. John H. Musser of Philadelphia said that we should not forget the possibility of cirrhosis of the liver as a cause of symptoms simulating those of gastric ulcer.

Dr. Thompson closed the discussion.

The Relation of Certain Stomach Disorders to Diabetes Mellitus.—Dr. John S. Sawyer of Cleveland read this paper. He said that treatment directed to the condition of the stomach, determined by examination of test meals, was given in nineteen diabetic patients for time enough, under suitable conditions, to afford usable results, and in all these cases there were noted almost immediate relief from thirst, hunger and excessive polyuria, with improvement in strength in many, and in several cessation of the glycosuria. The known duration of the glycosuria was from six weeks to five years. The youngest patients were fifteen to sixteen years old. The cases were of varying degrees, tested by standard diet. The first of the series came under treatment over five years ago. The measures adopted had been those usually employed in the special treatment of chronic glandular gastritis, varied according to the acidity and motor condition. Lavage had been signally beneficial, especially when used in the cases with motor insufficiency and hypochlorhydria. In several cases on stopping treatment the thirst and polyuria recurred, with prompt relief on resumption. In a few cases similar results were gained without lavage. These cases showed that thirst, hunger and polyuria were not as dependent on hyperglykemia as had been supposed, and that the stomach disorder was a factor of far greater importance in the treatment of diabetics than had been believed. A few tests of blood showed that hyperglykemia persisted without thirst or polyuria.

Dr. James Tyson of Philadelphia said that in his experience he had frequently noted the association of an active gastric disturbance associated with diabetes, and he thought this explained the efficacy of Fowler's solution, which might have an effect upon the stomach function. It was impossible that the acetone and diacetic acid that formed might have been the result of a catarrhal gastritis.

Clinical Notes on the Use of Nux Vomica, Especially in Certain Forms of Hypochlorhydria.—Dr. John H. Musser of Philadelphia told of those cases of gastric neurasthenia with hyperchlorhydria in which sedatives, antacids, etc., failed, but large doses of nux vomica gave relief. Ascending doses of the drug were given until its physiological effect was produced as shown by a slight stiffness in the neck and vertigo. When those symptoms appeared, the dose was reduced five or ten drops, and after a while the dose was again increased. Sometimes four or five months were required before the best results were obtained. The agent was given before meals, and the dose, of course, varied with the individual.

Umbilical Hernia as a Little Recognized Source of Abdominal Pain.—Dr. D. D. Stewart of Philadelphia read this paper, which dealt with the necessity of having in mind that hernia in the linea alba above the umbilicus, however small, might be a cause of recurring abdominal pain and various dyspeptic symptoms, the source of which, the hernia escaping recognition, was often regarded as obscure. These hernia, when small, were very commonly overlooked, the patient being treated for indigestion, gastralgia, gallstones, and the like. The importance of having in mind the most infrequent occurrence of umbilical hernia, and a careful search for it in abdominal examinations in all cases of pain, was pointed out.

Concerning the Obscurity of Diagnosis Sometimes Attending Stone in the Kidney, with Report of Cases.—Dr. D. D. Stewart of Philadelphia spoke of the recognition of certain observed cases of renal calculus, the symptoms of which were unusual and quiescent as concerned the kidney, and in which the stone or other affection of the kidney or ureter had not been suspected until they came into the doctor's hands. Certain cases simulating renal calculus—one was in an hysterical subject who had been previously operated on without result for suspected stone, and in whom a second operation had been contemplated—others in which the symptoms of [illegible] were due to inflammatory obstruction of the ureter were detailed and the points in the diagnosis of these cases were discussed.

Dr. J. N. Danforth of Chicago presented a calculus removed from the bladder of a female medical stud[illegible] 35 years. One year later several stones were removed from the kidney. One week after this a calculus of large size was removed from the left kidney and a large calculus from the right kidney at the post mortem. There was pus, albumin, phosphates, mortar-like deposits in the urine, but no pain up to the time of her death, and yet a calculus weighing nearly five ounces was removed from each kidney.

Dr. James Tyson of Philadelphia said that in the last two operations he had performed there seemed to be a condition which might explain the symptoms, at least in part; the cases presented tenderness in the kidney with intermittent or remittent or catarrhal condition of the ureter which was described as "a moderate amount and number of leucocytes and a trace of albumin." These cases came to operation and in each case there was what seemed to be what might be termed a "capsulitis," the capsule of the kidney being adherent and depressed in spots.

Dr. Forchheimer of Cincinnati said he had met with th[illegible] cases of similar nature in which the symptoms of tenderness were present, and other evidences of renal calculus, and yet the urinary signs showed nothing of the sort.

Dr. Frank Billings of Chicago said that the microscopical evidence of blood in the urine was of value, and spoke of a patient who had an acute pain in the right abdomen, which made him think of gallstones and perhaps perforation. Microscopically, blood appeared in the urine, a good differential point between appendicitis and calculus in the kidney. The *x*-ray he believed was many times as much a foil as it was a help in diagnosis, and was of but little value unless interrupted by one who was an educated physician. He referred to an interesting case of a woman seen within three years, who suffered from pain in the right side of the abdomen, and in which a diagnosis of renal stone was made. Subsequently an *x*-ray picture was taken by a so-called specialist, and the interpretation given of ureteral calculus, not far from the bladder. Other *x*-ray pictures were taken and in every instance shadows were shown which made the specialist believe he was dealing with stone in bladder. When Dr. Billings saw her he expressed doubt as to the existence of stone and suggested further examination. The result was the discovery of a bulbous pessary in the vagina.

Abdominal Tumors.—Dr. R. C. Cabot of Boston presented this communication, mainly one of figures from the records of the Massachusetts General Hospital. He reviewed 4,876 abdominal tumors as follows:

Tumors of the Abdominal Wall.—Hernia, 488; abscess, 79; sarcoma, 27; lipoma, 17; actinomycosis, 12; cancer, 6; hematoma, 4; fibroma, 3; tuberculosis, 2. Total, 638.

Tumors of the Liver.—Passive congestion, 1,288; biliary stasis, (?); biliary cirrhosis, 153; Hanot's cirrhosis, 0; cancer, 151; abscess, 51; lipoma, 46; Hodgkin's, 10; amyloid, 9; hydatid cyst, 8; syphilis, 8; fatty, 6; simple cyst, 6; actinomycosis, 3; sarcoma, 2; displaced, 2; tuberculosis, 1. Total, 1,702.

Tumors of the Spleen.—Myelogenous leukemia, 58; lymphatic leukemia, 13; biliary cirrhosis, 60; unknown cause,

26; chronic malaria, 16; cancer of the liver, 10; abscess of the liver, (?); Hodgkin's, 12; pernicious anemia, 3; myeloid, 2; sarcoma, 2; floating, 1; abscess, 0; tuberculosis, 0. Total, 206.

Tumors of Intestines with Peritonitis.—Cancer of the gut, 90; tubercular peritonitis, 33; intussusception, 17; acute obstruction, 20; dilated colon, 6; tuberculosis of cecum, 2; mesenteric tuberculosis, 3; fecal impaction, 2; omental cancer, 18; omental sarcoma, 4. Total, 195.

Tumors of the Kidney.—Floating kidney, 227; malignant, 27; tuberculosis, 41; abscess, 16; cyst, 10; etc.

Tumors of the Stomach.—Cancer, 285.

Tumors of the Pancreas.—Acute pancreatitis, 1; chronic pancreatitis, 1; cancer, 32; cyst, 3.

Tumors of the Uterus and Ovaries.—Uterine fibroma, 766; sarcoma, 14; tumor, 90; cancer, 609; ovarian cyst, 382; cancer, 43; fibroma, 11; sarcoma, 1.

They were also classified as follows: Abdominal tumors, 4,876. Of the abdominal wall, 150; of the liver, 1,702; of the spleen, 206; stomach, 265; pancreas, 37; intestines with peritonitis, 173; mesentery with omentum, 22; kidney, 378; retroperitoneal, 9; aneurysm, 25; uterus, 809; ovary, 437; broad ligament, 85; hernia, 488.

Dr. M. H. Fussell of Philadelphia wished to confirm what was stated regarding the chronicity of carcinoma of the cecum and he said he recently had seen a case lasting 14 months and probably longer.

Dr. W. S. Thayer of Baltimore thought that the frequency of fever in connection with cancer of the liver was a very interesting point. In many instances of rapidly occurring fever in sarcoma the diagnosis had been made of typhoid fever.

Dr. A. Jacobi of New York believed that the fever in such cases was due to the pressure upon the peritoneum; in cancer of the liver if the cancer would stop growing the fever would cease.

Dr. John H. Musser of Philadelphia believed that chronicity was a feature of cancer of the large bowel, not only of the cecum but other portions of the gut.

A Case of Cardiospasm.—Dr. Frank Billings of Chicago reported the case of a patient who had been sent to him with cardiospasm, with hypertrophy of the circular fibers and dilatation of the esophagus, about 500 c.c. He taught the woman how to pass a tube herself which she did unusually well. Sometimes the spasm would occur and she could not pass it for some time. In this way she fed herself. Dr. Sippy had worked out a plan of treatment and he was asked to demonstrate it.

A New Treatment of Cardiospasm.—Dr. Sippy of Chicago spoke of the varieties of this condition, primary cardiospasm resulting in dilatation or primary atony of the walls of the stomach without cardiospasm, primary atony of the walls of the stomach with secondary cardiospasm, disease of the pneumogastric nerves as described by Kraus, and that resulting from inflammation of the esophagus with reflex spasm at lower end of the esophagus; again, there were cases of congenital dilatation or sacculations in the lower part of the esophagus and subsequent cardiospasm. By far the most common was the primary cardiospasm. Balloons had been devised for dilatation of the esophagus, but they had not been successful because the pressure was not exerted at the right place. Dr. Sippy had devised a balloon with a central canal through which passed an ordinary esophageal bougie; the balloon was covered to prevent undue expansion. When distended with air it was about 14 cm., just a little more than the amount of dilatation required, and a little more than what was used by those who dilated from below. The patient had had this device applied twice and was very happy over the results, because for the first time in many months she had been enabled to partake of her food as other people did, and had had no discomfort [illegible].

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, Held April 27, 1905.

Dr. Chas. F. Adams in the Chair.

The Effect of X-ray Examination upon Pregnancy.—Dr. Sinclair Tousey said that the purpose of this paper was to consider what effect if any exposure to the *x*-ray had in preventing conception, or in producing abortion or still-birth. In this connection he said there were the observations of Dr. F. Tilden Brown to the effect that all of the *x*-ray workers, sixteen in number, who submitted to examination had shown either complete azoospermia, or a degree of oligospermia, or a degree of necrospermia which depended upon the length of time during which they had been radiologists. He did not know whether this came on gradually or as a sudden climax after some particularly long and intense action of the rays. Dr. Tousey said that this condition developed in *x*-ray workers who had never experienced the slightest dermatitis or other visible effects from the *x*-ray. He reviewed the literature showing azoospermia to have been produced by the *x*-ray with, in some instances, atrophy of the testis, but without external irritation. The observation of his own which he wished to record was to determine what effect, if any, would be produced by short exposures ordinarily required for *x*-ray pictures. The subject radiographed was a cat belonging to his household, young and strong, and who had been the mother of several healthy families. The pictures were taken at a time when she appeared to be "in heat," which was five or six weeks before she showed external evidences of pregnancy, and were continued up to the time when confinement seemed to be momentarily expected; during the last ten days no radiographs were made. The cat was never in the *x*-ray room except during the taking of the pictures. Each picture was taken with the cat lying on her left side upon the photographic plate, held there by his own hands resting upon the cat and equally exposed to the rays. A 12-inch induction coil was used, and usually a heavy anticathode Müller tube, No. 13, but for one picture a forty centimeter Friedlander water-cooled tube was used. The exposures were designed to be of the same strength and duration as for radiographing human tissues of the same thickness, but owing to the restlessness of the cat it was necessary to cut short some of the exposures. Measured by Holzknecht's chronoradiometer, the total exposure of the nearest part of the cat's body was ½ H., or four and a half minutes for the whole series. He said that 1 H. was one-third of the amount required at a single exposure to produce a visible reaction upon the human face. The result was naturally nil so far as the outward and visible appearance of the cat and so far as his own hands were concerned. The pictures were taken on October 6, 12, 16, and 21, November 18 and 29 (at which time the cat first presented positive external evidence of pregnancy) and December 17, 1904. Thirteen days after the last radiograph (December 30, 1904), three large and perfectly developed kittens were born dead. The cat was not again exposed to the *x*-ray, and on March 12, 1905 (two and a half months after the still-birth), four large and healthy kittens were born alive, and they are still alive and strong. He said it was very unusual for kittens to be still-born, and it had never happened before with this cat, and he thought it must have been due to the action of the *x*-ray. The conclusions to be drawn were that precautions should always be taken to prevent unnecessary exposure of the ovaries or testes; that where *x*-ray exposure of the reproductive organs was required, as in the treatment of cancer, even the existence of pregnancy might be disregarded as the full dosage required for a therapeutic effect did not necessarily interfere with the progress of gestation, or the viability of the child; that even the small dosage of the *x*-ray required for a radiograph sometimes might destroy the life of the fetus, but there was reason to believe that such exposures,

even if required on several different occasions, would not produce even temporary sterility.

A Report of Seven Cases of Cesarean Section.—Dr. James D. Voorhees read this paper. After detailing the histories of the seven cases, which occurred during his summer service at the Sloane Maternity Hospital and in private practice, he said that the operation of cesarean section was becoming more and more common and the indications more and more relative. There were reported during the year 1903 87 such operations, and 148 during the year 1904. During the first ten years and nearly three months of the existence of the Sloane Maternity Hospital, from January 12, 1888, to May 1, 1898, in 7,205 cases the records did not show a single woman delivered through the abdomen in the hospital. In looking over the first 15,541 confinements at the Sloane Maternity, he found that the fetal mortality for the induction of labor in contracted pelves was 21 per cent.; for medium forceps in contracted pelves, 20 per cent. of the babies succumbed; while in high forceps operations performed for contracted pelves, 57.6 per cent. of the babies died. In cases where version was performed for pelvic deformity, the fetal mortality wos 46.3 per cent. In five symphyseotomies performed by three different operators, one baby was still-born, a mortality of 20 per cent.; two of the mothers died from sepsis, a maternal mortality of 40 per cent. The records showed that 56 craniotomies were done for pelvic obstruction; in seven cases the fetus was alive, in four of which either its poor condition or the poor condition of the mother warranted the operation. Since May 1, 1898, to the present date 38 cesarean sections had been performed at the Sloane Maternity Hospital, 30 of these by Dr. Cragin, one by the late Dr. Tucker, and seven by the reader of the paper. Three patients died, giving a mortality of 7.5 per cent. All the babies were born alive except in one carcinomatous case. All maternity hospital statistics he said were unreliable because so many cases were admitted in labor, having been neglected by doctors and midwives outside. Yet, allowing for such adverse conditions, the statistics show that many infants were sacrificed, which with cesarean section undoubtedly could have been saved. The results for the child in the operations other than cesarean section, he said, were startling, and when obstetric operations carry with them such a tremendous mortality it should make the accoucheur hesitate attempting them. How different was it with cesarean section; practically all the babies being saved, perfect in every way and unharmed. One might say that we are not justified in recommending such an operation to save the life of the child, thereby increasing the risk to the mother, but it had been shown that this risk was slight, or not so much greater to her than when the other operations were performed. Placing the figures at a minimum and omitting all doubtful cases, he found that there was approximately a maternal mortality of 3 per cent. for the induction of labor, 1.8 per cent. for high forceps, 2.3 per cent. for version, 2.4 per cent. for craniotomy, and when symphyseotomy was performed 40 per cent. of the mothers died. Excluding one case of carcinoma of the cervix, which was moribund on admission, the maternal mortality for cesarean section was 5.1 per cent., and these were not selected cases, many of them being in labor when brought in. Other operators have better reports; in 172 operations performed by eight different surgeons, there was a mortality of barely 1.2 per cent. Deducting the moribund cases and those infected before operation, there would in all probability be a mortality of between 3 and 4 per cent. There was no question but that cesarean section was the only means of delivering a living child in marked degrees of pelvic deformity, and where tumors of various kinds blocked the parturient canal. Disputed points arose when the pelvis was only moderately contracted. Dr. Voorhees said he was unwilling to discard an induction of labor in the management of all contracted pelves. The fetal mortality at the Sloane Maternity for this operation was fairly high; 21 per cent. of the babies were still-born, and only 71 per cent. were discharged in good condition at the end of two weeks; but it should be remembered that a large number of the cases on which the percentage was based were delivered before the era of the cutting operation, even as long ago as 1888. From facts and figures he presented, and from his own personal experience, he still believed that labor could be induced with good results in slight to moderate degrees of contracted pelves, *i.e.* where any of the pelvic diameters was not less than 8 cm. The child, however, should have reached 36, preferably 38, weeks of intrauterine gestation, the head should not be too large, and the cervix should not be too long, closed, or tough. To determine just when to interfere and to estimate the exact relations of the size of the child's head to the pelvic canal, were both very difficult questions. Again, he said, we were confronted with the questions, will the uterine contractions be strong enough, and will a long and immature cervix soften up and dilate? He believed that Williams' plan of letting all cases "go to term, fall into labor, complete the first and enter the second stage to ascertain what nature can do," especially if gestation was prolonged, would cause more cesarean sections and other major operations than were necessary. He might save more babies, but the risk to the mother was increased. There were certain borderline cases where the pelvic deformity or contraction was slight or moderate, and here labor could be induced without injury to the interests of the child, most of them being born spontaneously. By the statistics given, he did not contend that too many difficult high forceps and versions were performed. If a version was performed, very few children at term survived after coming through an internal conjugate of 8 cm. He believed that if a version was done where the child was of fair size and the pelvis moderately contracted, especially in the justo-minor pelvis, most of the babies would be lost. With the low mortality rate of a cesarean section, a craniotomy, except on rare occasions, should never be an operation of choice if the child was alive. Symphyseotomy was an operation that certainly was on the decline; in 2021 operations performed by eight surgeons the maternal mortality was 14.4 per cent., and 18.5 per cent. of the babies succumbed. The only possible indication for this operation in the hands of a good surgeon would be in a case where the head was impacted well down in the pelvis after a prolonged labor, where the child was alive, and where forceps was unavailing. Whether Gigli's operation would ever supplant symphyseotomy and fulfill the earlier dreams of symphyseotomists was yet to be determined.

His conclusions were: (1) That cesarean section was only a dangerous operation when infection was present. (2) That there were too many fetal deaths from the other major operations. (3) That in view of the low maternal mortality the field for cesarean section should be broadened. (4) That in contracted pelves of a moderate degree (in the borderline cases) a late induction of labor was justifiable. (5) That when possible difficult versions, prolonged high forceps operations, and high forceps operations performed early in labor, should be avoided. (6) That craniotomy on a living baby was an operation only of necessity and emergency. (7) That symphyseotomy was an operation of the past.

Dr. Edwin B. Cragin said that those cases in which the obstruction in the parturient canal was so marked that the child could be delivered by cesarean section only need not concern the members of the section; in all such cases the operation was distinctly indicated. But, on the other hand, in those cases where the child could be delivered in other ways than by cesarean section, but with probable or certain death to the child, these were the cases that concerned them. In selecting any method one principle should always guide, *i.e.* that the future life of the mother should receive consideration. Any method which might save the child and yet which risked the life of

the mother should be discarded. The question that concerned him was this: "Had modern cesarean section so low a mortality and morbidity that we were justified in recommending it to patients and families?" Personally he believed it should be advised, if the mother and child were in good condition, in good surroundings and if good assistants were obtainable. The mortality of cesarean section, under these conditions, should not be over three per cent. With such a mortality he said we were confronted with the choice of two pictures, viz., a living child and a happy mother with three days of marked discomfort, or a dead child with a mother heartbroken and mentally depressed. Although cesarean section, performed by those skilled in abdominal surgery, was a simple operation, yet it should not be recommended and carried out except under the conditions mentioned; one could never foresee the dangers. He believed the field of cesarean section would spread not only in hospital, but in private practice.

Dr. J. C. Edgar told of the difficulties in diagnosis in the so-called borderline cases; it was exceedingly difficult in any given case to tell exactly what was the relative amount of space in the pelvis when moderately contracted; he knew of no way to ascertain the size of the head other than by passing the hand up. While cesarean section might be a simple operation he could not get away from the feeling that it was mechanically imperfect on the score of drainage; therefore, before doing this operation, he advocated dilating the cervix freely in order to obtain adequate drainage.

Dr. Austin Flint, Jr., said he was glad to note the conservative attitude assumed by so many even in an operation that carried so low a mortality as three or four per cent. This was an operation that could not be done offhand. At the Lying-In Hospital, among 10,000 cases, there were but three or four cesarean sections, one having been done for pelvic deformity and two for fibroids. Cesarean section should be resorted to only in those instances of pelvic deformities where one was sure that the child could not be born alive by the natural passages.

Dr. H. N. Vineberg said that one would seldom meet a woman or a husband who would give consent to this operation when the matter was placed fully before them. Although the mortality was given as three, four, or five per cent. he said that statistics could not be at all relied upon, and even with such a low mortality he had yet to meet a patient who would give consent to cesarean section. With a moderately contracted pelvis he believed the induction of premature labor was the operation of choice; here the chances of getting a living child were fairly good and a less serious operation was done. Personally he had a number of cases in which he had induced labor for lesser degrees of pelvic contraction, and so far every child had lived and the mothers had made good recoveries. He thought the operation of inducing labor had a wider field.

Dr. William S. Stone reported a few experiences with the object of illustrating certain points. His own experience with cesarean section was limited to eight cases, with the result of saving all the babies and losing one mother. In one case he reported the pathological condition was a hard tumor of the pelvis which almost completely blocked the birth passage. In another case there was a fibroid which plugged the pelvis. One of the most important things to bear in mind was the relation between the head and the pelvis; in the last ten days of gestation there was a hardening of the head. He believed the field for cesarean section, as well as that of inducing premature delivery, was broadening; this had been brought out by Norris of Philadelphia.

Dr. George H. Balleray protested against the impression which might be given out that cesarean section was an easy operation. In those cases in which there was a question as to the extent of the pelvic deformity he advised giving nature a chance first; one should wait until the second stage of labor was reached before interfering.

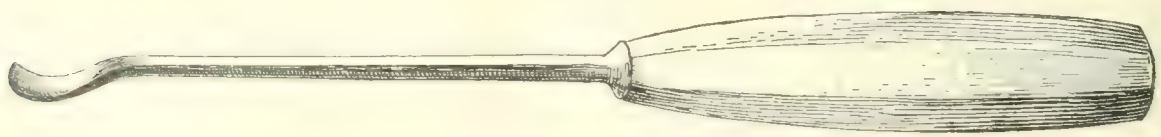
Dr. Voorhees closed the discussion.

New Instruments.

THE FRONT-BENT GOUGE IN CRANIAL SURGERY.*

By H. SOHIER BRYANT, M.D.,
NEW YORK.

This tool has long been in use among wood carvers for working out under a design to give it more relief. A year and a half ago I noted its possibilities if applied to bone surgery, especially to cranial work. Since that time, I have used it with much satisfaction in all my operations on the skull. It shortens in a very great degree the time of operating, it



lessens the danger of untoward accidents to the patient, it relieves my mind from much of the strain consequent upon the impending danger to the patient, and is the means of sparing the patient the repeated blows of the mallet which is generally used in this work. The good results are also shown in the shorter convalescence, compared with the usual time, which the patients pass through. The instrument is a gouge with a long shaft, and a handle that rests comfortably in the hand. Near the tip the blade is bent forward sharply. Two sizes are used, 3/16 and ¼-inch blade.

The instrument is better than a trephine on account of its safety and quickness of action. In order to bore a hole through the bone, it is rotated on its longitudinal axis. When the excavation is deep enough to hold the end of the gouge, the handle is rotated and swung at the same time, thus cutting on the sides and floor of the depresssion. The instrument cuts along the surface to be removed by a slow forcible movement of the cutting edge. This action is accomplished through the convexity of the curved blade which rests on the sides of the bony wound and acts as a fulcrum, while the shaft is swung like a pump handle. To enlarge an opening already made, the blade of the gouge is directed around the opening, the sides of which act as a fulcrum. To remove bone from the side or the floor of a bony cavity, the edge of the instrument is applied to the point to be removed, and with the convexity

* Shown before the Surgical Section of the New York Academy of Medicine, April 7, 1905.

of the blade resting on adjacent bone, the desired fragment is readily cut off.

The danger of slipping through is reduced to a minimum because the force applied is never parallel to the direction of the excavation, but at right angles to it. The cutting edge of the instrument is not sufficiently sharp to cut soft tissues, but slides over them, and thus avoids any danger of wounding the dura mater or venous sinuses, etc.

With the use of this instrument, the time of convalescence has been found to be from a third to a quarter shorter than would be expected under the usual conditions. This lessening of the time of convalesence can, I think, be largely attributed to the saving of the patient from the jar inflicted by the blows of the mallet in cranial work. If anyone doubts the serious disturbance resulting from the use of the mallet, let him apply a blunt instrument to his skull and let some one pound the instrument with a mallet in the usual way in which it is done in bone surgery. I think that he will admit that this procedure is not good for his health, or for his peace of mind.

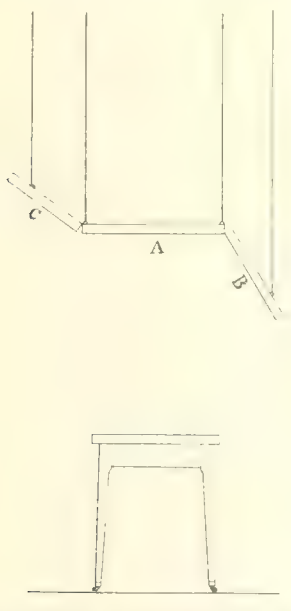
48 West Fortieth Street.

A MIRROR DEVICE FOR FURTHERING PRACTICAL TEACHING OF OPERATIVE SURGERY.

By FREDERIC GRIFFITH, M.D.,
NEW YORK.

The device consists of a single, large plane mirror, or two or three placed side by side, and suspended ing-table as he fruitlessly sought a vantage point of view, gave me the idea which I believe worthy the consideration of those engaged in teaching surgery to bodies of students.

The device consists of a single, large plane mirror or two or three placed side by side, and suspended above the operating-table. By raising or lowering the ends of the glass the proper angle of reflection to



Mirror (A B. C.) in position suspended above the operating table.

afford students sitting in the back rows of seats adequate view of the operative field may be obtained. The criticism that such reflected images would be confusing to the spectator, may be met with the answer that a reflected image is better than none, which observation is borne out by the generally accepted value of the ordinary throat-mirror.

While modern surgical amphitheaters are not generally constructed to seat two or four hundred students as heretofore, it is nevertheless a fact that even where but thirty or forty are accommodated, only a comparatively small number seated upon the first three or four rows gain an unobstructed view. Where the students are permitted to collect about the table possibly only six or eight of them see with satisfaction. It would seem, therefore, that a trial of the mirrors set up as suggested would prove them of distinct value.

Dyspnea in Pneumothorax.—Hofbauer states that in unilateral pneumothorax the resulting dyspnea is not entirely due to the collapse of the lung on the injured side, but is, in addition, the result of great interference with the function of the other lung as well. Owing to the instability of the mediastinum, which is ordinarily maintained in its position by the balance of negative pressure existing in the two pleural cavities, when one pleura is opened the mediastinum is at once drawn several centimeters toward the uninjured side. This lung is, therefore, also caused to collapse to a considerable degree, though enough of pulmonary activity still persists amply to supply the needs of the body without giving rise to dyspnea, were it not for another factor. The dyspnea of pneumothorax is not inspiratory, but expiratory, and depends on the fact that the lung, on retracting, has sacrificed a large part of the elastic energy needed to expel its air content during expiration, and ventilation of the air passages is, therefore, dependent on the accessory muscles of expiration, which are few and not well adapted to the work.—*Zentralblatt f. innere Medizin.*

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending May 13, 1905:

	Cases	Deaths
Measles	742	14
Diphtheria and Croup	312	36
Scarlet Fever	235	13
Smallpox	6	1
Chickenpox	120	.....
Tuberculosis	474	195
Typhoid Fever	37	3
Cerebrospinal Meningitis	136	88
Typhus Fever	.....	.....
Yellow Fever	.....	.....
Cholera	.....	.....
Totals	2,071	350

Carcinoma Arising After Twenty Years in a Vaccination Scar.—Wm. B. Crawford describes this case. The patient was a colored farm-hand, 68 years of age. The family and personal histories were negative, except that the patient had had frequent attacks of malaria. Twenty years before he had been vaccinated upon the right arm. A scar about the size of a quarter resulted. No tendency to hypertrophy in the scar and no keloid formation had been noted. The patient was a moderate drinker, but denied syphilis. Eight months before admission to the hospital the scar became painful and tender, although there had been no injury. The scar also began to increase in size, and the patient consulted a physician. Within a few months after these symptons the scar broke down, with a resulting foul-smelling lesion. Loss of strength and flesh became rapid and decided. On admission the upper third of the arm showed a necrotic, foul mass, covered with a purulent discharge, which bled readily. The axillary glands and a chain down the sides of the chest were enlarged. These glands were discreet. The general appearance of this lesion was that of an infected keloid. The temperature was 100°, the pulse 96, and respirations 22. The urine was negative. At operation the arm was disarticulated and removed with an extensive dissection of the axillary space and side of the chest. The patient never recovered from the shock of the operation and died twenty-two hours after.—*The Georgia Practician.*

Diphtheritic Paralysis.—M. McCrory declares that the term diphtheritic paralysis is scarcely broad enough to cover all the nervous symptoms of the disease, for these are not always strictly paralytic in nature. He sums up his observations as follows: Signs of early affection of the nervous system, such as disorder of the mechanism of swallowing, loss of knee-jerks, or occurrence of vomiting, are of particularly grave omen, while as to prognosis in cases of paralysis coming on at a later period, it is generally favorable, most cases terminating in recovery without much treatment. Yet each case has an element of danger, and the symptoms which should more especially cause anxiety are the occurrence of vomiting, disturbances of the circulation, or paralysis of the diaphragm or intercostals; cardiac failure offers the greatest danger; and in these cases there is little doubt that it is the innervation which is at fault. In all cases with which the writer has met, where the heart has failed, there have been other signs, such as vomiting and abdominal pain, strongly supporting the idea of a nervous origin for the cardiac symptoms. Tonics are needed to fight the anemia and debility of these cases. In cases of cardiac failure, brandy or champagne, ether or ammonia, digitalis or caffein, carefully given, may be most important. The nasal tube for feeding may be necessary, and all such conditions which would indicate this must be carefully watched. Antitoxin does not protect the nerve centers when they have been acted on by the toxin of diphtheria.—*The Medical Standard.*

Fluorescence of the Urine in Diabetes.—Schilling refers to an observation first made by Strzyzowski, to the effect that the urine of diabetics, if rich in sugar, displays fluorescence twenty-four to thirty-six hours after the addition of formalin, if kept at room temperature. The author, in investigating the matter, found that the phenomenon always appeared in urine containing over four per cent. of sugar, but when only 0.5 to 2.5 per cent. is present, no fluorescence develops. Experiments to determine the nature of the substance causing the phenomenon showed that it is not due either to aceton, diacetic acid, or B oxybutyric acid, and the probability is that it depends on some coloring matters that are still unknown. The assumption is that these are formed in some gland or tissue in consequence of perverted metabolism, and, reaching the urine, are rendered fluorescent in the presence of formalin.—*Zentralblatt f. innere Medicin.*

Treatment of Hemoptysis.—Francis Hare was led to try inhalation of amylnitrite in hemoptysis on physiologic grounds. He argued that the peripheral vasodilator influence of the drug would cause a fall of blood-pressure in the aorta, left ventricle, left auricle and ultimately in the pulmonary arterioles. He gives the results obtained in the first nine cases (8 tuberculous, 1 mitral). Sixteen attacks of hemoptysis were treated by amyl nitrate; in all save one, the bleeding ceased in less than 3 minutes, for the most part instantaneously; in the one exception there was an immediate retardation, but cessation did not occur for 10 minutes. The drug does not interfere with cough, hence retention of blood and subsequent septic pneumonia are obviated. The treatment is safe and easily applied by the patient himself.—*American Medicine.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ended May 13, 1905:

INTERMITTENT CLAUDICATION AND ALLIED SYNDROMES DUE TO ANGIOSCLEROSIS OF THE EXTREMITIES.*

BY J. RAMSAY HUNT, M.D.,

NEW YORK.

CHIEF OF THE NEUROLOGICAL CLINIC AND INSTRUCTOR OF NERVOUS DISEASES IN THE CORNELL UNIVERSITY MEDICAL COLLEGE; NEUROLOGIST TO THE CITY HOSPITAL; ASSISTANT PHYSICIAN TO THE MONTEFIORE HOME.

THE sclerosis of the arteries and veins of the extremities and the abnormal vasomotor states sometimes associated, form a subject which well illustrates the intimate relationship of neurology and the broad field of internal medicine, some of its phases even transporting us into the domain of surgery.

While the syndromes resulting from angiosclerosis and angioneurosis of the extremities are many and varied, the underlying pathological changes are those so familiar to us all—the arteriosclerosis, the obliterating endarteritis, and the senile calcification of the arterial tree.

Among the more or less clearly defined clinical pictures dependent upon vascular disease of the extremities may be mentioned: (1) The intermittent claudication (Charcot); (2) some forms of erythromelalgia (Weir Mitchell); (3) some types of symmetrical gangrene (Raynaud's disease); (4) the spontaneous gangrene of the extremities; (5) the arteriosclerotic neuritis from obliteration of the vasonervorum. For the production of these various clinical types special factors are essential, of which the more important are: The degree and nature of the vascular process; the localization and predominance in certain vascular areas; the neurotic element or the accompanying vasomotor neurosis.

Great importance must be attached to the associated vasomotor instability as a determining and often dominating factor in these cases. A simple obliteration of an artery would have as a result the so-called spontaneous gangrene. If such obliteration were symmetrically distributed, a picture similar to Raynaud's disease would follow. If, however, to the arterial disease a vasomotor instability is superadded, with a tendency to vasoconstriction or vasodilation, the symptoms of intermittent claudication or erythromelalgia would result. The so-called arteriosclerotic neuritis, a very rare manifestation, is merely an unusual predominance of the process in the vessels of the nerve trunks, inducing widespread degeneration of the nerve fibers and the symptoms of an irregular, progressive neuritis.

The kindred nature of these various clinical types receives abundant confirmation in a similar pathological anatomy, in their occasional combination, and a somewhat rarer alternation, *i. e.* the disappearance of one syndrome and its replacement by another, and, most important of all, in a very striking tendency to a common termination, *the dry gangrene.*

In fact, the important practical lesson taught by a consideration of this subject is to regard all these various manifestations in the light of a distinct warning and forerunner of this unhappy termination.

As the intermittent claudication has received but scant attention in this country, and even less in Great Britain, and as the subject is one of great practical importance, a somewhat detailed description is ventured upon, including four personal observations.

Historical.—For the name and the first description of this affection we are indebted to Charcot. His first publication appeared in 1858, and described in a most graphic manner a complex of symptoms, which he christened Claudication Intermittente; use was also made of the term Paralysie Douloureuse Intermittente. The autopsy revealed an aneurysm of the right iliac artery, the vessel having been occluded by a thrombus for a short distance below. Charcot also remarked the resemblance between this group of cases and a similar condition observed in horses by veterinarians. (Bouley in 1831, Rademacher in 1838, Böther in 1839, and others.) Animals suffering from this disease, which we term springhalt, after covering a short distance, are seized with sudden weakness and stiffness in the hind legs, which become absolutely rigid. After a short rest the spasm relaxes and the function of the extremities is restored. In these animals arteriosclerosis and calcification at the bifurcation of the aorta and in the iliac arteries was found interfering with the free circulation of the blood in the parts below.

Further contributions from the pen of Charcot appeared in 1886, 1887, 1891, and 1892, crystallizing and enlarging the clinical picture and adding materially to our knowledge of the etiology. Other communications from French observers appeared in 1873 by Sabourin; 1890, Delaunay; 1892, Magrez; 1894, Levet, and Bourgeois, in 1897.

Strangely enough, this very striking, and, as has been demonstrated by subsequent experience, not uncommon affection, received but little attention in other countries. It was not until 1892 that Elzholz, and in 1895 that Goldflam, recorded cases in Germany. In 1898 however, Erb, in a masterly exposition, comprising a complete analysis of the literature and a most able discussion of the whole subject in all its phases, inaugurated a new era for the intermittent claudication, and insured it a permanent and important niche in the pantheon of disease. While Charcot attached the greater importance to disease of the larger arterial trunks, as did also the veterinarians, Erb demonstrated in the clearest manner possible its dependence in the vast majority of cases upon sclerosis and obliteration of the smaller arterial branches and terminals.

Since Erb's publication many monographs have appeared in German literature showing the frequency and growing importance of the affection.

*Read at a meeting of the New York Society of Internal Medicine, January 18, 1905.

Among these are Higier, in 1900, recording 23 cases; Hagelstam of Helsingfors, in 1901, recording 7 cases; Idelsohn, in 1903, recording 14 cases. In this country the first report of a case was made by Putnam of Boston in 1901. Subsequent case reports followed by Dana, in 1902; Riesman, 1902; Walton and Paul, 1902; Levy, 1902; Patek, 1904, and Burr, 1904. In the literature of Great Britain no contribution to this subject could be found. The natural inference is that in this country and Great Britain either the malady is rare, or it has not yet attained widespread recognition and importance.

Several names, more or less descriptive in nature, have been suggested to supplant the original, as suggested by Charcot. Intermittent muscular paralysis (Grossman); myasthenia angiosclerotica (Higier); angina crusis (Walton and Paul); dysbasia angiosclerotica intermittens (Erb). The intermittent claudication seems, however, to have been firmly fixed by usage, and at present still finds most favor, although the dysbasia angiosclerotica, as proposed by Erb, is more descriptive and has a more general application.

Etiology.—The disease is much more frequent in men than in women. While the etiology is still obscure and somewhat speculative, a number of causative factors, both general and special, have come to be recognized. All those general causes favoring the development of angiosclerotic changes naturally assume a prominent place—advanced life, alcoholism, syphilis, gout, and nicotinism. Diabetes was present in a certain number of cases. Among the special causes having a more or less local influence may be mentioned exposure to excessive cold, flat foot (Idelsohn), arterial compression by a truss, and aneurism (cases of Charcot, Barth, Mannaury). Some observers, notably Oppenheim, attach great importance to the neurotic temperament, the so-called neuropathic diathesis. Others again would seek a cause in the hereditary or congenital insufficiency of the cardiovascular apparatus and its controlling nervous mechanism. Erb, who has had unusual opportunities of observation, recording 57 cases in all, attaches the greatest importance to excessive smoking and exposure to excessive cold as direct excitants of the vasomotor irritability and spasm.

Pathology.—Our knowledge of the pathological anatomy of this affection has been derived very largely from the study of amputated extremities. (Charcot, Erb, Marinesco, Goldflam, Laveran, Panas, Dutil and Lamy.) Only a meager number of autopsies have been recorded. (Cases of Charcot, Elzholz, Magrez, and, recently, Erb.) The findings have been practically uniform, and may be summed up in the one word, angiosclerosis. All forms of arterial changes are met with, the obliterating endarteritis of Friedländer, the senile calcification, the arteriosclerosis of Gull and Sutton, the periarteritis nodosa of Kussmaul and Maier, with and without obliteration and thrombosis, but all tending to produce a common evil, a diminution in the caliber of the vessel, with consequent circulatory embarrassment. The veins not infrequently show analogous changes, but in a lesser degree, the phlebosclerosis and endophlebitis. These changes are all more marked in the smaller arterial branches and terminal vessels of the extremities, and they frequently show a symmetrical distribution on the two sides. It must be emphasized, however, that arteritis, aneurism, and thrombosis of the larger trunks have been found in quite typical cases.

In the more advanced stage of the obliterating process secondary changes of a trophic nature frequently occur. The muscles may become atrophied and show extensive areas of degeneration and sclerosis (Marinesco case). The nerves may present more or less diffuse degeneration from occlusion of the vasonervorum, this in turn leading to degenerative muscular atrophy (cases of Joffroy and Achard, Dutil and Lamy), or a portion of the extremity may be thrown off by the process of dry gangrene. It is this termination which unites these cases with the symmetrical, senile, and spontaneous forms of gangrene.

These are the structural changes found in the class of cases under discussion. But such alterations are very commonly present where not a trace of intermittent claudication has been observed, so that another and most important factor deserves consideration, of a purely functional nature, and may be termed the vasomotor element. The variations in arterial tone, the alternate contraction and relaxation of the vessel wall under the influence of various internal and external stimuli is well known. The flushing of the face and sudden pallor, the coldness of the hands and feet under the influence of a sudden emotion is a common experience. It is this vasomotor irritability, this spasm of the arteries of the extremities which contributes so largely to the production of this peculiar syndrome, and accounts, in part, for the sudden restoration of function after a paroxysm. Some observers even (notably Oppenheim) suggest a purely functional form of the disease, or one in which the structural alterations of the vessels play an entirely subordinate rôle.

While the vasomotor element deserves all the importance accorded it, it should not be overlooked that a mechanical impediment to the circulation alone, perhaps sufficing during rest, but insufficient for the increased demands of activity, may of itself cause symptoms of claudication.

It is generally admitted that the symptoms are ischemic in origin, the manifestation of a temporary anemia of the muscles, nerve endings, and other structures. In this connection reference is often made to the experiments of Stenson and others who, by compression of the aorta, produced paralysis and anesthesia in the parts below.

The exact relation existing between the organic changes in the vessels and the vasomotor irritability is still speculative. Whether the tendency of the vessel wall to vasomotor spasm is the direct consequence of arterial disease from implication of the intrinsic nervous mechanism, or merely an independent vasomotor neurosis superadded to the other condition. Three factors must be recognized in the production of the claudication ischemia. One, constant and organic in nature, diminishing the caliber of the vessel, and two factors, inconstant and functional, the tendency to vasomotor spasm and the increased demand upon the circulation of the part during activity.

Symptomatology.—After a consideration of the various clinical features and peculiarities of dysbasia angiosclerotica, that which is perhaps most striking and most characteristic is the intermittent character of the symptoms. An absence of pulsation in the pedal arteries and evidences of circulatory disturbances in the lower extremities are of scarcely less importance. The patient suffering from this affection, while at rest, either in the sitting or recumbent position, is unconscious of any disability; the extremities are freely movable and are free from any abnormal sensory manifestations. He feels that he could rise and walk indefinitely. In fact, it is usually possible for him to rise and start off at the usual pace without any ill effects, but gradually, in from

five to ten, twenty or thirty minutes, or even longer, varying with the severity of the case, the symptoms of claudication appear, and increase in severity with the effort to proceed. At last further progress becomes distressing, or even quite impossible, and an enforced rest results. Gradually the symptoms of distress grow less, the legs resume their natural feeling and power, and in a very few minutes the pedestrian is able to pursue his way, only to halt again as the time limit of his toleration is reached.

The symptoms induced during the period of activity, while differing somewhat in individual cases, are strikingly similar. Usually the first indications of beginning trouble as the paroxysm approaches is a sense of weight and heaviness, a feeling of fatigue and pain in the leg. This is soon followed by coldness and pricking sensations, and the etremity becomes numb and weak. If activity is maintained the muscles stiffen and become painfully cramped, and the characteristic limping results, or locomotion may even become quite impossible from the intense, marble-like rigidity which follows (abasia). Thus weakness, painful cramps, paresthesia, and stiffness may be regarded as the essential accompaniments of the paroxysm, although other and often very curious sensations are sometimes graphically described by the patient, as: "A sensation of water rushing through the leg"; "as if the leg were being sundered from the body"; "a bursting feeling in the calf"; "as though I dragged a cannon shot about in my leg." Sometimes scalding or burning sensations are complained of, or the hot sensation of very intense cold.

If the feet and legs are inspected after a prolonged effort, or even in more severe cases in the dependent position alone, evidences of circulatory disturbance are very obvious. They are congested and swollen, with evidences of mottling and cyanosis, and are palpably colder than normal. In cases with marked vasomotor irritability the feet and toes may even assume a "dead" or waxy hue from the high degree of arterial spasm. In the more advanced cases the intense burning pain in the toes, which may be a glossy red or cold and purple, indicate the beginning of total arterial obliteration, with consequent gangrene.

Objective changes in the pulsation of the pedal arteries are of great importance in these cases. In the vast majority of cases the posterior tibial and dorsalis pedis arteries, one or both, are either quite pulseless or weaker than normal. To determine their constancy under other conditions Erb examined 750 cases, at all ages and suffering from various ailments, with a positive result of 99 per cent. With so small a proportion of negative cases, some of which may be accounted for on the ground of anomalies of distribution, the foot pulses may be practically regarded as fixed and constant, and their absence as evidence of a pathological state. Goldflam and Walton and Paul have carried out similar investigations on a smaller series of cases (200), with practically the same results (Goldflam, 99 per cent., Walton and Paul, 96 per cent.).

Changes are not infrequently met with in the superficial veins of the extremities, minute dilatations and varicosities, and an increase in the number of visible venules. In some cases thrombosis of the veins has been observed.

Wasting and atrophy of the muscles occasionally occur. This is often only the atrophy of inactivity, but true muscular degeneration and sclerosis may result from obliteration of the vessels. While the symptoms are often confined to a single extremity, in the majority of instances both limbs are involved, but rarely in the same degree. No adequate explanation has been offered for the greater frequency of the affection on the left side.

While the typical picture of intermittent claudication is as outlined above, the paroxysm during activity and complete freedom during rest, certain exceptions may be mentioned. In the more severe cases, in which the obliterating process is well advanced, or the patient has abused the "time limit" for a considerable period, sensory symptoms and weakness may be present more or less constantly, and may give rise to errors in diagnosis. In this group of cases sharp lancinating pains shoot through the legs and the calves may be constantly stiff, swollen, and tender.

As might be inferred from the general nature of the underlying process, the symptoms of intermittent claudication may occur in other arterial distributions of the body. One or both arms may present rarely the characteristic symptoms of the disease, usually associated with objective changes in the pulsation of the arteries at the wrist. Cases presenting this distribution have been recorded by Nothnagel, Hagelstam, Dana, Burr, and Massaut. An unusual localization was observed in a case recorded by Brissaud. A severe burning pain would regularly appear on the anterolateral aspect of the left thigh after walking twenty minutes, always disappearing after a short rest. Autopsy revealed an exquisite arteriosclerosis of the branches of the femoral artery in Scarpa's triangle. In two cases, in addition to the other symptoms, the pudendal artery was found occluded, and had produced during life rectal disturbances and impotence in the case of Luxemburg, and incontinence of urine in Burr's case.

The syndrome of intermittent claudication, viz., function perfect at rest, but impaired during activity, is by no means confined to the vessels of the extremities. It has long been thought that the paroxysms of angina pectoris were referable to a similar state of the coronary arteries. In recent years cases with autopsy are recorded showing the occurrence of this syndrome in the brain, kidney, retina (Wagenmann), and intestines (Schnitzler and Ortner).

Indeed, so general would its application seem at present that *dyspragia intermittens* (Ortner) has been proposed as a generic term, indicating the intermittent disturbance of function.

Perhaps the most circumscribed type of the affection is found in an isolated muscular localization, associated with recurring cramps and pains in certain definite areas. The frequency of these muscular spasms in old people, and their dependence upon arterial disease, has been emphasized by Walton and Paul. Thoma and Erb likewise refer to many of the so-called rheumatic pains of middle life and their possible dependence upon vascular conditions.

In discussing the pathological anatomy mention was made of secondary nerve degenerations, arteriosclerotic in origin, due to obliteration of the vasonervorum. In rare instances, notably in the cases of Schlesinger, Joffroy and Achard, the localization of the obliterating process in the neural arteries was so extreme, and the resulting degeneration of nerve tissue so great as to give a distinctly neuritic coloring to the clinical picture. These cases presented the picture of a slowly progressive multiple neuritis, of very irregular course, with occasional acute exacerbations and associated with paralyses, atrophies, objective sensory disturbances and electrical changes.

Before leaving the subject of symptomatology reference must be made to the rare occurrence of

certain atypical, or even paradoxical forms described by Erb. In these weakness and fatigue in the legs may occur, without the characteristic intermission or even the necessity of resting, or activity, instead of aggravating, may cause an amelioration of the symptoms.

Diagnosis.—The diagnosis in well-marked and typical cases is easy. The nature of the motor and sensory manifestations, their intermittent character dependent upon activity and rest; the accompanying evidences of circulatory disturbances and absence or feebleness of pulsation in the pedal arteries should render the recognition of this affection comparatively easy. Early and atypical cases may present greater difficulties and suggest disease of the central or peripheral nervous systems, or even some purely local condition, such as flat foot, tarsalgia, meta tarsalgia, and podalgias of gouty origin. It is needless to insist that in every case a thorough examination of the nervous system is absolutely essential. It should also be an established routine practice in all nervous cases of doubtful nature involving the extremities to examine carefully the pedal arteries and note the condition of the circulation in these parts.

Prognosis.—The prognosis as regards cure is unfavorable. Many cases, under appropriate treatment, have shown considerable improvement, while others resist every known method, and continue their downward course, terminating in gangrene. Those cases in which the vasomotor element is well marked, and those due to obliterating endarteritis of syphilitic origin, are most amenable to therapy. In general, it may be said that, under appropriate measures much may be done towards arresting the process and warding off indefinitely the threatened gangrene.

Treatment.—One of the most important elements in treatment is rest. These patients should never be allowed to transgress their time limit, *i.e.* the period of time elapsing while walking before the appearance of the claudication. They should, as Charcot advised, walk watch in hand, with slow, measured step, and frequent intervals of rest.

From time to time prolonged periods of rest in bed are also advisable, as allowing a better collateral circulation to be established in areas poorly nourished, and also favoring the establishment of a more stable vasomotor tone, so important an element in these cases.

Of the internal remedies, potassium iodide in moderate doses finds great favor, as in other manifestations of arteriosclerosis. Where syphilis is suspected it should naturally be pushed to the point of toleration. Also cardiac tonics, especially those with little action on the vasomotor system, such as strophanthus. Drugs bearing a special influence on vasoconstriction, such as digitalis and ergot, should be studiously avoided. Nitroglycerine has been recommended in these cases for its effect on the arterial walls, but without very brilliant results. Warm foot baths and galvanic foot baths are highly recommended by Erb for their vasodilator effect, and should be given a trial in all cases. On the contrary, very hot baths and naturally cold baths should never be employed.

Idelsohn, in his series of 22 cases, found an associated flat foot in eight cases. He is inclined to regard this as an etiological factor of importance and recommends its careful correction. Its exact relation to the affection is not clear, but his suggestion that the circulation in the foot may be impeded by sinking of the arch, or that possibly by stretching of the nerves a state of reflex vasomotor irritability is induced, well merits consideration.

Report of Personal Observations.—Case I. (Referred by Dr. Henry Russell.) The patient is a widow, 58 years of age, of unusually strong constitution and hale and hearty appearance. She has never borne any children. Her parentage is English, and on both sides of her family for several generations gout has existed in its most exquisite form. The patient herself has never suffered from this affection. So far as her memory goes no member of her family has suffered from any of the graver mental or nervous diseases. It is interesting to note in this connection that both the patient and a brother have been sleepwalkers from an early age. Two sons of this brother were also somnambulistic. This tendency was never outgrown in the patient's case, and even up to the present time a change of surroundings or any unusual stress or worry is sufficient to excite a night ramble. In her younger days these somnambulistic episodes were frequent and of some gravity. It was not uncommon to find her in this state walking the streets. Objects were frequently hidden, letters written and other complicated acts performed. She has always enjoyed exceptional health, and her mode of life has been one of unusual care and moderation. In her diet she has been rather addicted to red meats, and for many years she has taken daily six large cups of strong tea, of alcoholic beverages only on the rarest occasions. During the latter years of her life she has had many trials and anxieties, culminating about five years ago in a distressing episode, at which period her present malady began. She had always been fond of walking, took a very quick step, but rarely exceeded from three to five miles a day. Until the beginning of her present trouble she had never suffered with cold hands or cold feet or other evidences of vasomotor instability. In 1885 she abandoned the use of the circular garter.

In the winter of 1900, after walking from a quarter to a half mile, she first noticed that a slight stiffness and numbness would develop in the calf of the left leg. She frequently rested on this account, and found that after a few minutes it passed away, so that it became her habit to break a journey or a shopping expedition by these short waits. These symptoms gradually grew worse, so that in time it became necessary to shorten the distance, and for any longer effort to increase the period of rest. About the same time the right leg presented similar symptoms, but of a trifling nature and slight in comparison. It sometimes happened that when no good opportunity was offered for a rest she would try to brave it out and push on, but to her consternation the left leg would become painfully cramped, absolutely stiff and immovable, and she would have to remain standing where she was. Several times while in this condition she simply collapsed helplessly on the sidewalk, but after a short rest was able to proceed without difficulty. Her condition continued to grow worse, so that eventually only a very short distance could be traversed (from five to ten minutes) before the appearance of painful cramp, numbness, and rigidity in the affected leg. At times very sharp lancinating pains would shoot through the legs, especially at night. The feet were almost constantly cold, and in a dependent position would assume a bluish, mottled hue. In December, 1902, she slipped on the ice and fractured the external malleolus of the left leg, and while under treatment for this passed through a severe attack of pleuropneumonia. The convalescence was complicated by thrombosis of the veins in the lower extremities, first in the right leg, a day or two later in the left, preceded by severe pain and the development of tender lumps

along the inner side of the thighs, and followed by a considerable edema of both legs. After recovery from this illness, in May, 1903, the legs were much worse, the feet and ankles would become puffed and edematous, and she complained of almost constant pains, numb feelings, and cramps in both legs, but much more severe on the left side. It was at this time that she first came under my care, and I am much indebted to her physician, Dr. Henry Russell, for his observation of the case previous to this.

Status præsens, May, 1903.—Complains of constant numbness and aching pain in the left calf, especially along the perineal side. In this region there is a painful throbbing sensation, "as if a boil were about to burst." She also experiences at times a sense of great weight and heaviness in the calf, as if a cannon-ball were embedded in the muscle. Sharp pains dart through the legs, often of such severity as to cause a scream, and the muscles of the leg become knotted in painful cramps. The feet and ankles are swollen and cold, and on standing they assume an angry red discoloration. After walking about three minutes the steps become slow and tottering, the muscles of the calf stiffen, the outer side of the leg, sole of foot, and toes become numb and dead, and it is only with the greatest effort, associated with dyspnea, that the left leg can be moved any further. The same disturbance, but much milder, is present in the right leg. The knee jerks and ankle jerks are present on the two sides and exaggerated. Deep pressure on the calves causes the same pain as is observed in neuritic affections. The examination of the nervous system, however, is entirely negative. Sensation over the lower extremities is normal. No pes planus. The heart is free from murmurs and regular, the first sound of good muscular tone, and the second aortic moderately accentuated. The radial pulse is exceptionally small, in view of the large physique and florid appearance of the patient, but the walls are without a trace of thickening. The urine is free from albumin and sugar.

The condition noted in the pedal arteries is as follows: Right posterior tibial, good pulsation; right dorsalis pedis, not palpable; left posterior tibial, feeble pulsation; left dorsalis pedis, good pulsation. No difference in the pulsation of the femoral and popliteal arteries could be noted on the two sides. After walking five minutes no appreciable change was noted in the character of the pulsation in these vessels. No muscular atrophy and no muscle quivering (myokymia) was observed in either leg, and the calves measured the same on the two sides. The thighs escape entirely, and the complaint is of the leg below the knees. At times, however, when seated in a hard straight-back chair, a painful rigidity develops in the gluteal muscles, especially of the left side, analogous to that described in the legs, and disappearing quickly in the recumbent posture. At times, while seated at meals and not obeying the first warnings of the gluteal spasm, the buttocks become so painfully stiff that she is unable to rise alone and has to be literally pulled out of the chair. This localization of the painful spasm never occurs in walking or in standing, nor in the recumbent position, but only while sitting.

She was removed to a sanatorium and placed at absolute rest in bed for one month. At the end of the first week nearly all the distressing subjective symptoms had disappeared, the swelling of the feet and legs had subsided, but the dorsal aspect of the toes was still reddish, paling on pressure.

A very slight thread-like pulsation became apparent in the right dorsalis pedis artery. Treatment consisted essentially of sodium iodide in ascending doses, nitroglycerin, alkaline waters, anti-gout diet and daily hot salt sitz baths at 100° F. At the end of a month the beneficial results of these measures became apparent. She could walk from ten to fifteen minutes with only a moderate sense of stiffness and numbness; if, however, the exercise was prolonged beyond this time painful cramps and rigidity would develop. After an additional two weeks she was allowed to return home where practically the same measures were instituted. She was advised never to transgress her time limit of fifteen minutes, to take frequent rests and for at least one-half of the day to maintain the recumbent posture. For six weeks after leaving the sanatorium she complained bitterly of painful cramps and stiffness in the gluteal region while sitting, but these gradually disappeared. The patient has been under continuous observation up to the present date. Her condition varies from time to time, any exacerbation can usually be traced to prolonged over-exertion and inattention to the warning pains and numbness. If the law of fifteen minutes is disobeyed, the legs ache and feel almost continuously numb, the ankles puff up and the feet become cold and cyanotic. She dreads the cold of winter and always rests with the hot water bag at the feet. Quite recently her condition was aggravated by the worry and exertion attending a change of residence. The old symptoms returned in all their intensity, and in addition, there appeared two swollen areas, very tender to the touch, one just above the internal malleolus and another over the upper third of the tibialis anticus muscle. Over these the skin was quite hyperesthetic. The swelling in the tibialis anticus muscle was tender only on direct pressure, movement of the muscle as in flexing the foot was unattended by pain. These tender swellings as well as the distressing subjective symptoms disappeared after an enforced rest.

December 12, 1904. Pulsation in the pedal arteries is as follows: Right dorsalis pedis, very faint and thread like; right posterior tibial, strong pulsation; left dorsalis pedis, full, strong pulsation; left, posterior tibial, fair pulsation but distinctly weaker and of smaller volume than the right.

Good pulsation in both femorals and popliteals. Repeated examination of the urine was negative. No change in the cardiac condition, the radial pulse is exceptionally small and soft. Dyspnea on exertion.

April 1, 1905. During the past three months patient has received treatment as follows: Moderate doses of the iodides and bromides, tincture of strophanthus, galvanism to the lower extremities, and hot salt foot-baths, under this regime some improvement has been effected, she sits with greater ease and walks with more freedom, but I cannot say that her time-limit (15 minutes), has been materially lengthened.

Case II.—Referred by Dr. C. E. Campbell. The patient is a Hebrew, forty-two years of age, a storekeeper by occupation. Family history is negative. The man himself is of a quick, nervous temperament, but had enjoyed excellent health up to the onset of his "leg trouble," in the winter of 1902. He is careful in his habits, very moderate in the use of alcohol and tobacco, and denies syphilitic infection. The urine was examined repeatedly and was always normal.

Early in the winter of 1902 he observed that the sole of the left foot and the left leg would become numb during a long walk. The muscles of the calf would stiffen and the foot would become swollen. At such times it was his custom to sit down, unlace his shoe and rub the foot, all trace of the trouble disappearing in about five minutes. He would then re-

sume his journey, repeating this procedure as often as necessary. If, however, he continued without resting, the leg would become more and more stiff, and the numbness extended up the thigh. A very unpleasant sensation would then develop, as if the whole left leg were being thrown off or separated from the body. Paresthenia and stiffness would also develop after long-continued standing in his shop, but never so severe as in walking. Quick relief was always obtained in the sitting or recumbent position. The right leg was unaffected. On awakening in the morning, the leg always felt perfectly well. He feels the cold in both feet, but the left foot is always the colder, both subjectively and to the feel. The left foot sometimes swells about the ankle, but he has never remarked any bluish discoloration. It is possible for him to walk from one-quarter to one-half mile with comparative comfort.

Status præsens.—July 31, 1903. The lower extremities are normal on inspection, no atrophy, no fibrillation, no discoloration. There is no appreciable difference in the temperature of the two sides. The knee jerks and the Achilles jerks are exaggerated and equal on the two sides. No flat foot.

There is no evidence of any involvement of the central or peripheral nervous systems. Heart action is good, no murmurs; the aortic sound is sharp. The radials are not thickened.

Pedal Arteries.—Dorsalis pedis: a full pulsation on both sides; posterior tibials; good pulsation in both posterior tibials, but the right is appreciably weaker than the left; popliteals, pulsate equally on the two sides; femorals, also pulsate well, rather fuller on the left side; the difference, however, is not marked.

The patient was cautioned about over-exertion, and the same measures taken as in Case I. He returned to his home in Corning, N. Y., where he continued this treatment for several months, with some amelioration in the symptoms, and has not come under my personal observation since. In response to an inquiry dated December, 1904, I received the following reply: "The trouble is still entirely in the left leg, especially the sole of the foot and the calf of the leg. I can walk about half a mile without much annoyance; then the prickling, electricity-sensation, pain and stiffness develops, especially in the calf of the leg. Standing for a time also brings it on. The foot does not swell or change color. If I rest about five minutes, all the symptoms disappear. There is no material difference in my condition summer or winter. My physician advised me to wear a plate in the left shoe, which seemed to giv me some relief but my condition remains about the same."

Case III.—(From Prof. Dana's Neurological Clinic, Cornell University Medical College.) A bartender aged sixty years, no venereal history, excessive use of alcohol. For the past twenty years averages ten to twenty drinks a day, in addition to this frequent sprees lasting one or two weeks. For twenty years has smoked ten cigars a day, also chews tobacco (half an ounce in a day). His occupation behind the bar and in damp cellars, has entailed prolonged exposure of the feet to cold and wet for many years.

The first indication of his present trouble was a numbness and coldness appearing in the right great toe about two hours after beginning work in the morning. This was first noted about five years ago and has persisted ever since, gradually involving the whole foot to the ankle. The feeling is one of stiffness and weakness in the right foot and toes, associated with stinging pains, numbness, and prickling sensations. The foot also feels cold and is cold to the touch. In the morning on awaking there is not a vestige of any disturbance, but after walking one-quarter to one-half a mile the stiffness and numbness are induced, varying in intensity with the temperature, and season of the year. In winter all his symptoms are much aggravated and frequent rests are necessary. After resting about fifteen minutes with the feet held before a fire, nearly all symptoms disappear. It is possible for him to walk a mile or even a greater distance, although with much discomfort. The leg above the ankle and the thigh are not involved. Until six months ago the left leg had been perfectly free. At this time a numb, cold feeling made its appearance in the left great toe and gradually extended to the other toes. The disturbance here is likewise described as a stiffness and weakness in the toes with much pain and prickling sensations gradually extending up the foot. As in the right foot it is brought on by standing and walking

Fig. 1. Skiagram of leg in intermittent claudication, showing deposits of lime and calcareous plates in the walls of the dorsalis pedis and posterior tibial arteries.

and is relieved by resting. With the exception of the symptoms just described and occasional rheumatic seizures this patient enjoys fair health.

Status Præsens.—The temperature of both feet is distinctly lower than normal. They are free from any swelling, but on standing the veins stand out with undue prominence and there is moderate cyanosis. The venules of the skin of the feet and legs are the seat of minute dilatations and ectasies.

The pulsation in the dorsalis pedis on both sides is absent and the artery may be felt beneath the finger as a minute rounded cord. A fair pulsation is present in the posterior tibial arteries. While this was the most constant condition noted in the pedal arteries, it must be remarked that on one occasion (a very cold day), no pulsation could be felt in the posterior tibials behind the internal malleolus and often the pulsation was very feeble. At no time was a pulsation felt in either dorsalis pedis artery. The pulsation of the femoral

arteries and the popliteals was of normal volume and equal on the two sides. The general indications of arteriosclerosis are manifest. Arcus senilis, hypertrophy of the left ventricle, accentuation of the second aortic tone, thickened radial with increased tension, a trace of albumin in the urine, no sugar. A careful examination of the nervous system, including motility, sensation and reflexes fails to show any abnormality whatever. The calves of the legs show no atrophy or fibrillary twitchings and present equal measurements on the two sides. He is not flat-footed and there is no tenderness along the nerve trunks.

Radiographs of the right foot and leg show deposits of lime in the posterior tibial and dorsalis pedis arteries delicately outlining their cause. See the illustration.

Case IV.—(Cornell Neurological Clinic).—The patient is forty-nine years old and has been an iceman for thirty-two years, an occupation which exposes the hands and feet to the influence of cold and wet almost continuously. He has indulged excessively in alcohol for many years, as a result of which had gastritis and hemorrhages two years ago. Smokes six cigars a day and chews tobacco almost without intermission. In 1879 acquired syphilis, ulceration on the right leg in 1880 and a perforation of the nasal septum in 1885. In September, 1903, was removed to the alcoholic pavilion of Bellevue Hospital in delirium tremens, where he remained eight weeks. During a part of this time restraint was necessary and he was bound in the usual manner by sheets attached to the wrists and ankles. The first symptoms of the present affection were noticed immediately after discharge from the hospital and were attributed by the patient to the restraints used. He complains of a numbness and "dead" feeling in the toes and dorsum of both feet which become stiff and weak in walking. The left side is worse than the right. The stiffness extends as high as the middle of the calf and is produced and aggravated as are the sensory manifestations by standing and walking.

Last summer he could walk a mile without resting, with discomfort to be sure, but at present (winter), a quarter of a mile renders a rest necessary preferably before a fire, when the more distressing symptoms disappear in about fifteen minutes. The feet feel cold and numb most of the day and swell considerably after standing and walking. They also become blue and mottled in appearance. At times sharp, shooting pains are felt in the feet and legs. On rising in the morning the legs feel perfectly well and natural but after standing and a short walk, the numbness, coldness, and stiffness reappear.

Status Præsens.—Both feet and ankles are swollen and cyanosed. The dorsal surface of the feet and the front of the legs present numerous small venous dilatations and varicosities. The toe-nails of the left foot are marked with transverse ridges. A full pulsation in the dorsalis pedis is present on both sides. A faint pulsation is apparent in both posterior tibial arteries. Good full pulsation in both femorals and in both popliteals. Not infrequently on a cold day it was quite impossible to detect any pulsation in the posterior tibials.

The general signs of arteriosclerosis are present, and the urine contains a faint trace of albumin but no sugar. The motility, sensations and reflexes are normal. No tenderness over the nerve trunks, no wasting or fibrillary twitchings in the muscles of the leg. Radiographs of the left foot and leg show an exquisite deposit of lime salts in the walls of the posterior tibial and dorsalis pedis arteries distinctly outlining their course.

Remarks.—The cases just narrated present the typical pictures of the intermittent limping in varying degrees of severity. The ages of the patients were fifty-eight, forty-two, sixty, and forty-nine years respectively. The etiological factors noted were. Case I.—Neurotic temperament, gouty heredity, anxiety, and tea. Case II.—A moderately nervous temperament. Case III.—Excesses in alcohol and tobacco and prolonged exposure of the feet to cold and wet for many years. Case IV.—Syphilis, excesses in alcohol and tobacco, and constant exposure of feet to cold and wet for years. Exciting cause: Restraint in alcoholic delirium.

Both legs were affected in Cases I, III and IV, but of unequal intensity. In Case II the left leg alone was involved. Pulsation was absent or diminished in one or more of the pedal arteries in Cases I, III and IV. In Case II the anomalous condition was found of a diminished posterior tibial pulsation on the unaffected side. The *x*-ray photographs taken of Cases III and IV, the walls of the posterior tibial and dorsalis pedis arteries are distinctly outlined by calcareous deposits. According to Sänger this method has a certain prognostic importance, for, as was pointed out by Charot, cases dependent upon calcareous deposits are less amenable to treatment, than the arteriosclerosis and the endarteritis. In all the cases something has been gained by treatment, in the amelioration of symptoms and the lengthening of the "time-limit," but in none was a very definite improvement noted. On the other hand, since the institution of a proper regime and treatment, the malady does not appear to have progressed materially.

To Summarize Very Briefly.—Angiosclerosis of the extremities in its gravest form, uncomplicated by a vasomotor nerousis leads to spontaneous gangrene. If the angiosclerosis occurs in combination with a vasomotor instability and a tendency to vasomotor spasm, the syndrome of intermittent claudication results. This is characterized by the development of sensory (pains and paresthesia), and motor (weakness and rigidity) manifestations during functional activity with a rapid and permanent restoration to the normal during rest. The syndrome, however, has a wider and more general application to the whole circulatory mechanism and has been observed in relation to various organs of the body (heart, intestines, brain, kidney, and eyes).

THE GARDENER'S SPADE DEFORMITY AND THE SILVER-FORK DEFORMITY IN FRACTURES OF THE CARPAL END OF THE RADIUS.*

By JOHN B. ROBERTS, M.D.,
PHILADELPHIA.
PROFESSOR OF SURGERY IN THE PHILADELPHIA POLYCLINIC

Much has been written in recent years about the pathology and treatment of fractures of the carpal end of the radius. These lesions continue, nevertheless, to be badly treated by a great number of practitioners. It seems impossible to convince the profession that restitution of the normal concavity of the palmar surface of the lower portion of the radius is essential for comfortable convalescence and perfect cure. This must be accomplished, even if great force is required to disentangle the fragments and thrust the lower piece into its normal relation with the upper. Such force is demanded in most cases, and the surgeon who fails to employ it does not reduce the fracture. Pain, stiffness of the wrist and fingers, deformity and a protracted convalescence result from the defective surgical treatment.

Fig. 1.—Silver-fork deformity in fracture with backward displacement. (Diagrammatic.)

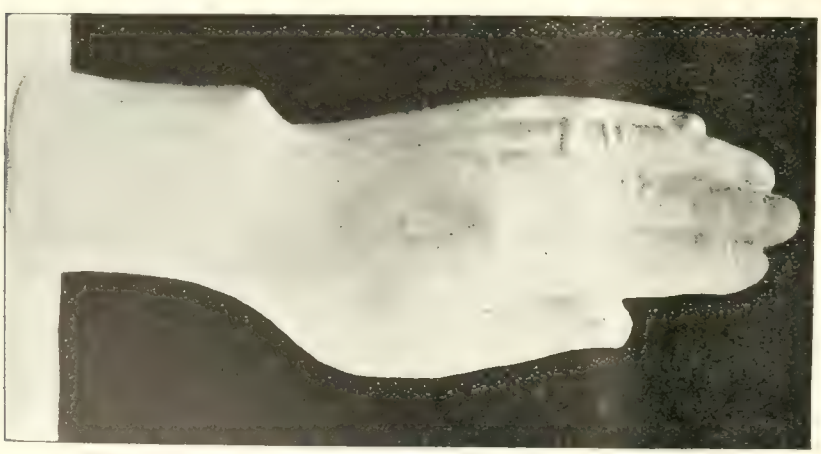

Fig. 2.—Gardener's spade deformity in fracture with forward displacement. (Beatson's case.)

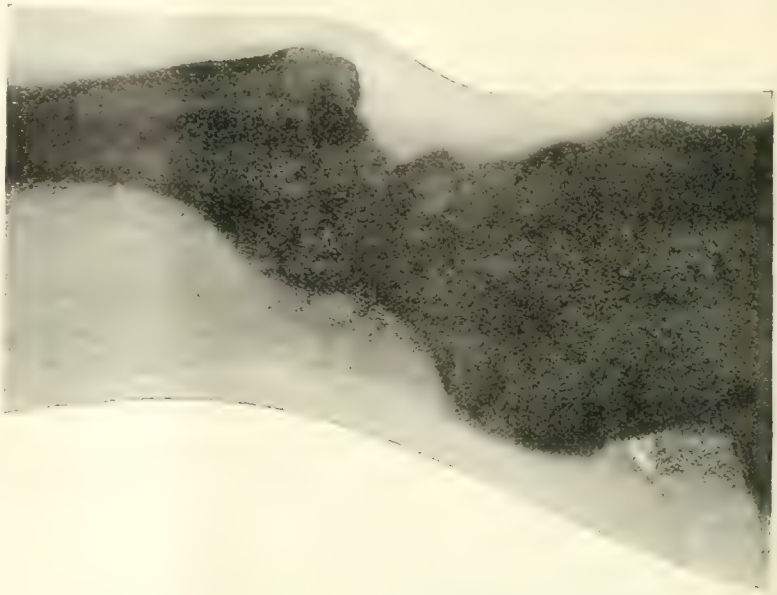

Fig. 3.—Skiagraph of gardener's spade deformity. (Author's case.)

These injuries are the fractures of all others, in which "setting" of the bone must be promptly and efficiently done, by the immediate application of a very considerable degree of manual power. Ignorance of the anatomical shape of the lower third of the bone and timidity, in using sufficient force, are the chief factors in the imperfect surgical treatment.

The so-called "silver-fork deformity" of the fracture, with displacement of the carpal fragment backwards, must be absolutely overcome before the fragments may be assumed to have been properly coapted. Very often I do see cases in which the reduction has been only partially successful, because sufficient force has not been applied. The fracture in the same part of the radius with displacement in the opposite direction, namely, forwards, is frequently unrecognized and, therefore, remains unreduced. This injury is much less frequent than that in which the lower fragment is thrust towards the dorsal aspect of the forearm. It, however, occurs sufficiently often to be taken into consideration in the diagnostic examination of all injuries near the wrist-joint.

It is undoubtedly often overlooked, probably because the lower fragment, driven forwards, lies between the flexor tendons and the concave palmar surface of the radius. Little protuberance is, therefore, made by the displaced piece of bone, which simply fills up, as it were, the hollow of the radius above the carpus.

The general deformity, which in teaching I call the "gardener's spade deformity," is, however, very characteristic, even when the inflammatory swelling of the forearm and hand is great. It is very different from the "silver fork deformity" of the fracture

* Read before the College of Physicians of Philadelphia, March 1, 1905.

with backward displacement of the carpal piece. As will be seen by these photographs and casts, from the Mütter Museum, the planes of the forearm and hand are related to each other almost exactly as are

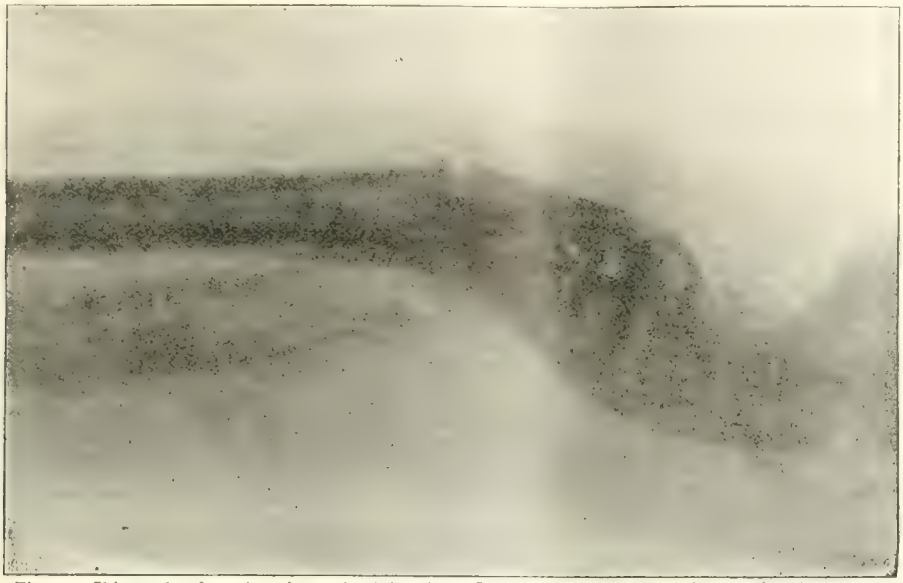

Fig. 4.—Skiagraph of gardener's spade deformity. Line of fracture further from wrist than usual. (Author's case.)

the planes of the handle and blade of the gardener's spade. This deformity is not at all like the silver fork contour given by the fracture with backward displacement, which has a marked elevation at the back of the forearm, due to the displaced lower fragment. That elevation is conspicuous, because the dorsal surface of the normal radius is practically level. It has no hollow as has the palmar surface.

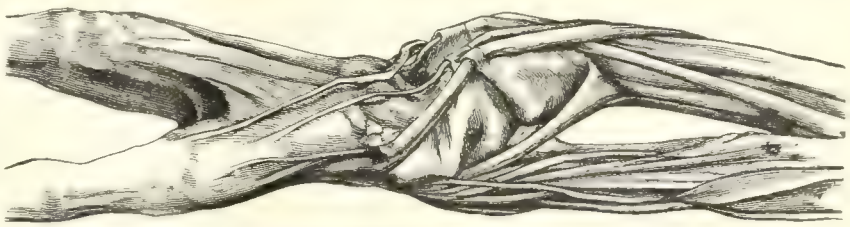

Fig. 5.—Dissection of gardener's spade deformity. (Museum of the New York Hospital.)

Both fractures are usually produced by falls, in which the force of the impact is conveyed to the

Fig. 6.—Bony specimen of gardener's spade deformity. (Museum of the Royal College of Surgeons in Ireland.)

lower end of the radius. Whether the lower fragment is thrust backwards, as it is usually, or forwards, as it is occasionally, depends upon the resultant of the forces.

The degree of displacement dorsad or palmad of the carpal piece varies with the amount of the vulnerating force and the strength of the bone. Therefore, the degree of resemblance to the gardener's spade or the silver-fork also varies; but it is very decided in both instances when the lower fragment is markedly thrust out of place.

In both lesions the styloid process of the radius is apt to be carried upward towards the elbow. As a result, an imaginary line joining the ulnar and radial styloid processes crosses the axis of the forearm at nearly a right angle or with the radial end nearer the elbow than the ulnar end. In the normal arm this interstyloid line is farther from the elbow on the radial than on the ulnar side. The width of the forearm just just above the wrist-joint is apt to be increased in these fractures, because of the displacement towards the elbow of the radial side of the carpal fragment. The hand, on account of the change in the plane of the articular surface of the base, may be voluntarily carried further to the radial side than is normal. The ulnar head is very prominent at the back of the wrist in fracture with forward displacement; but not so in the break with backward displacement. In both forms of injury, however, the ulnar head may be very prominent at the ulnar *edge* of the wrist; because the shortening of the broken radius may give a displacement of the hand and carpus toward the radial side of the limb.

Examination with the *x*-ray will often aid in the diagnosis; though usually it is not needed, if the examiner knows the anatomy of the parts and is familiar with the symptoms of both forms of fracture. It must be remembered, too, that the *x*-ray picture is after all only a diagrammatic outline of the varying densities and consequent shadows. The tube placed over the dorsum may give very nearly identical results on the photographic plate, in fracture with the carpal piece displaced either backwards or forwards. A second skiagraph should be taken through the forearm with the ulnar edge towards the photographic plate. This is illustrated by a skiagraph here exhibited, which was not under-

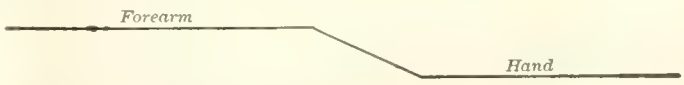

Diagram of Deformity in Fracture with Forward Displacement

stood by the doctors, who first saw it and the injury. The examination of the wrist some weeks after injury made it clear to me that the case had been a fracture with forward displacement, which had not been recognized and, therefore, was not reduced. A skiagraph showed well the displacement upwards

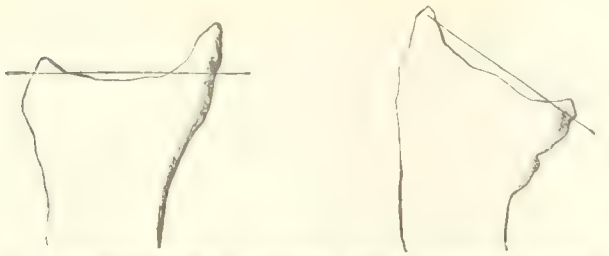

Fig. 8.—Diagrams showing change in plane of articular surface of radius after either form of fracture.

of the radial styloid process; but did not show in which direction the lower fragment was thrust. The gardener's spade deformity and palpation of the wrist on the palmar aspect definitely proved to me the character of the bony lesion.

The treatment of both fractures is easy, if the doctor will only use enough force to disentangle the carpal end and compel it to assume its normal posi-

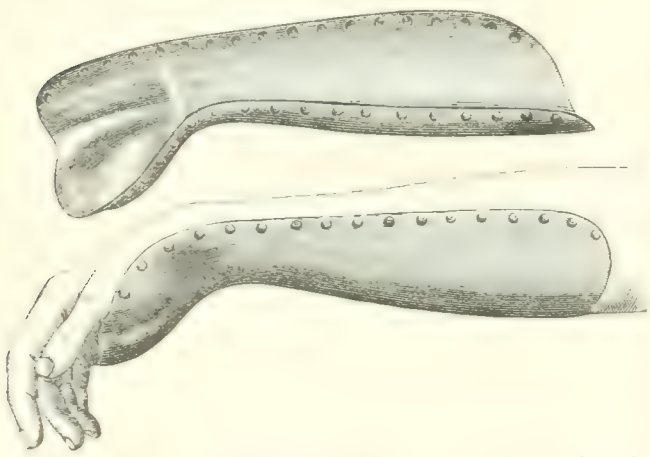

Fig. 9.—Moulded metal splint maintaining concave palmar surface of radius.

tion. This forcible reduction is essential. A light straight splint on the dorsum of the forearm and hand, or a moulded splint on the palmar surface is usually the proper retentive dressing after reduction has been thoroughly accomplished. The concave palmar surface of the lower third of the radius must be maintained after forcible reduction has re-estab-

lished it. Plastic splints are probably preferable to wooden ones; though wood, metal, gypsum, or adhesive plaster all make good retentive appliances, if the fracture be thoroughly reduced and the professional attendant is discreet in the selection and application of his splint material. The simpler the dressing is the better it is, as a rule

MY CHANGES OF VIEW IN APPENDICITIS WORK.*

By ROBERT T. MORRIS, M.D.

PROFESSOR OF SURGERY IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

My first operation for appendicitis, or perityphlitis, as it was generally called at that time, was on March 15, 1888. The subject of operation was just beginning to be advocated strongly in New York by Sands, McBurney, Bull, Weir, and other leading surgeons. Discussion on the subject referred chiefly to the treatment of the abscesses of appendicitis, which Sands said were usually extraperitoneal. The accepted treatment at that time consisted chiefly in opening the abscesses, flushing the cavities, and employing large rubber or glass drains, together with more or less gauze packing. During the next four years I operated in a number of cases of appendicitis with abscess, and employed the commonly accepted methods of treatment. Results were pretty bad. Patients made slow recovery, with weak points left for the subsequent development of ventral hernia; or they died of acute peritonitis or of slow septicemia.

My first planned operation for removal of the appendix was on April 24, 1902, although a number of other surgeons had already done such planned operations. In 1892 I removed seven appendices. Four were gangrenous. Two were the site of acute exacerbations of infection, and one was a quiescent "interval appendix." Six of the patients lived. One died of ileus which developed suddenly on the sixth day after operation. Morphine was almost universally employed by the physicians and nurses at that time, for controlling the symptoms subsequent to operation, and I began to forbid its use altogether in cases that were under my control. My views on the subject of morphine in this connection have changed somewhat, and the drug is now given cautiously in certain cases in which there is such a degree of restlessness that the patient does not start off well after operation. Even in such cases morphine is a double-edged sword, because it puts the eliminating organs at rest along with the sensory nerves.

During this year of 1892 I employed long incisions, peroxide of hydrogen flushing for abscesses of appendicitis, the wick drain composed of absorbent gauze rolled in gutta percha tissue in cigarette fashion, catgut sutures for separate suturing of tissue planes, and more or less gauze packing. The stumps of amputated appendices were ligated and buried, and a good deal of unnecessary surgery was forced by me upon some patients for the accomplishment of this step in technic.

Changes of view led to making incisions that were not "bold and free, and masterly in the stroke," for it seemed to me that there was a tendency to do too much surgical injury in these cases, and it was noted that short incision patients started off more quickly toward comfortable recovery. Peroxide of hydrogen flushing seemed to me to be the keynote to success in abscess cases, but later experience has shown that it is valuable chiefly in the way of neatness, and that we can safely leave pus to be disposed of by the wick drain and by the peritoneal lymphatics. There has been no change of view concerning the desirability of catgut suturing of separate tissue planes of the abdominal wall. The

*A paper read at the meeting of the Society of Alumni of Bellevue Hospital, February 2, 1905.

technic of burying the stump of the appendix has been abandoned since the publication of Seelig's article on the subject in the Annals of Surgery last year, and several minutes of time have been gained for each operation in consequence.

Gauze packing has been discarded altogether, on the ground that it is a foreign body, that it causes ileus by direct mechanical effect, and excessive lymph exudation which leads to troublesome adhesion formation. Shock is caused by removal of gauze packing, and a serious defect is left in the abdominal wall in spite of provisional sutures.

When iodoform gauze is employed patients often suffer or die from iodoform poisoning, and unless the urine is examined for free iodine the symptoms of iodoform poisoning are commonly thought to be symptoms of septicemia.

On discarding gauze packing it was at once observed that patients made remarkable recovery from operation, and that the gauze packing had been worse than useless. This view was in direct opposition to the consensus of opinion among authorities, and probably would not have been upheld in any court of law in the country during a period of several years.

In this year of 1892 I employed blunt dissection, but had sloughing of margins of external oblique aponeurosis in two cases, due to free separation of that structure no doubt. The method was dropped, and not taken up again until the publication of McBurney's description of his method. Since that time I have employed the "gridiron" method, not only in early infection and interval cases, but in practically all cases. It gives great protection against subsequent hernia formation.

In 1893 I devised a plan for making a short route for the escape of bowel contents in cases in which fecal fistula was anticipated, by suturing the cecum to the abdominal wall at the site of the incision. It was thought that this procedure would be useful also in preventing hernia formation. My views on that point have changed, and it no longer seems desirable to fix the cecum in an abnormal position. Fecal fistulæ care for themselves pretty well if we employ skillful neglect in their treatment, and postoperative ventral hernia should be almost unheard of if we have right ideas about suturing the divided structures. In 1893 I employed another resource that had been advocated as a protection against ventral hernia; the use of buried silk worm gut sutures. Silk worm gut is not encapsulated kindly in the tissues like catgut, kangaroo tendon, silk or silver wire, and my knots began to work out, weeks, months and years after they had been introduced. If I ever have a nightmare it will probably consist in a view of a row of influential patients bearing silk worm gut knots on a charger. Aside from the use of gauze packing the most serious mistake that has ever come into my appendicitis work was the employment of silk worm gut for buried sutures. In 1893 my favorite incision had been made of a standard length of an inch and a half, for interval and early infection cases, no matter what the extent of adhesions. It was noted that patients after this incision were regularly out of bed by the seventh day after operation, and ready to leave the hospital by the tenth day. It was one of my house surgeons who suggested that this was a week and a half, and others in a spirit of fun have added the instrument and a half and the dollar and a half to the formula, without my sanction. My views on the desirability of the short incision not only have not changed, but now it has been adopted for almost all of my work in abscess and peritonitis cases, as well as for interval and early infection cases. My belief is that one should take all of the room that he requires for successful work, but that he should get to require little room as quickly as the fingers can be trained to do better work when not confused by the eyes. One can easily extend the incision if necessary to do so. My friend Joseph Price says that when he gets among complicated adhesions he wants some one to tie a handkerchief about his eyes so that he cannot even see the surroundings of the room. In the language of the convert who shortened his prayers, "Them's my sentiments." In several hundred complicated appendicitis cases I have had a mishap but once when working by touch, and in that case it simply amounted to severing the artery of the mesappendix, so that the incision had to be lengthened for the application of forceps. Adhesions were often very confusing in earlier days when it was necessary to work by sight, and there was danger of injury to the bowel, ureter, or iliac vessels, but no such danger appears in the statistics after one has learned to work by touch.

In 1893 I began to note the advantage to the patient of quick work, and gradually reduced the time of operation to an average of twenty minutes, then to fifteen minutes, and it is now common to have the time from the first incision to the last suture occupy not more than seven or eight minutes in complicated cases. It has always been a rule to get the appendix out, on the ground that at least ten per cent. of cases would carry concretions, and a much larger percentage of cases would have late complications from mucous inclusions, if the appendix were left. Sometimes in a moribund patient, or when working among unfavorable surroundings, it is best to simply open abscesses, and to do expediency work expeditiously, but this has always seemed to me to be unfortunate, and my views have never leaned toward the policy of opening abscesses at one operation, and removing the appendix subsequently. I will not disagree with authorities who argue for this practice, but simply express personal views in the matter.

The question of operating upon moribund patients has always seemed to me to be one of morals rather than one of policy, and I have operated upon every patient who was still breathing when we got to the house or to the hospital. The pulse could not be counted in some of the cases, but it is surprising to note the effect of an intravenous saline infusion of fifteen hundred cubic centimeters given in advance of operation, and the effect of letting out a flood of toxins by a five or ten minute operation in many of these cases. One might as well not operate at all in such cases if he contemplates spending thirty minutes at the work, or of proceeding before the intravenous saline infusion has been given, and he must count upon having his chief death rate in this class of cases, at best.

The question of separating adhesions freely in a search for the appendix or for multiple abscesses is one in which my views have changed. At first I had the classical fear of the peritoneum and reasoned also that as adhesions were nature's protection it would be well to respect them. Later it was found necessary in many cases to separate adhesions freely in getting the appendix or in searching for multiple abscesses, and it was noted that no harm resulted from exposure of the normal peritoneum. It was evident that the local leucocytosis and other elements of protection had been called out sufficiently to guard the field, and for awhile it was my practice to break up all adhesions purposely. My final decision is that adhesions re-form at separated points in acute infection cases, so that nothing is gained by

separating them, but that it does no harm to open freely into the normal peritoneal cavity in cases in which one is hunting for something among adhesions. After noting the degree to which the peritoneum was guarded against infection I dropped the idea of flushing out the peritoneal cavity with saline solution in most of the cases in which the abdomen contained septic fluid. It seemed to me that almost everything that we had been doing conscientiously added to the severity of the operation and that the nearer we could come to leaving the patient alone the better. Even large masses of lymph coagulum remaining attached to the bowel are now left undisturbed. After dropping out of my practice the features which seemed to have a special death rate of their own—gauze packing, iodoform gauze, long incisions, and the expenditure of time in unnecessary detail of work—I published a report on a series of one hundred consecutive appendicitis operations, with a two per cent. death rate. Thirty-four of the patients had abscess and various stages of gangrene and peritonitis. Twelve of the patients had acute infection with gangrene of the inner coats of the appendix in some of the cases, but without external abscess formation. The rest of the patients in the list had quiescent forms of appendix trouble. Of the two patients who died, one was properly a case of gangrene of the ileum, several feet of which had slipped through an adhesion band from an old appendicitis, but the case had to be included because I removed the remains of the appendix incidentally. The other death was in one of the moribund patient operations.

The effect of the publication of this list of cases was to cut down my practice to a very serious extent indeed, and one writer in the MEDICAL RECORD for December 12, 1896, went so far as to say that such figures were "vainglorious cheats," and that operation must have been refused in many cases for the purpose of getting misleading statistics. As a matter of fact I had operated upon every appendicitis case to which I had been called during the period covered by the statistics, with the exception of two patients who were dead when we got to the house.

The methods that were advocated in my paper were generally held to be unsafe and dangerous. In the *Medical News* for July 2, 1904, Dr. L. W. Hotchkiss states that in one of the hospitals with which he is connected, and where many emergency cases are received, his death rate up to 1898 in appendicitis cases treated by the accepted methods of the day had been 31 per cent., but after taking up "unsafe and dangerous methods" he had not lost a single patient in his last seventy-two cases, although among the number there were twenty-six gangrenous appendices, with or without perforation, and fifteen gangrenous appendices with advancing peritonitis. At the 1904 meeting of the American Medical Association, Dr. Ochsner of Chicago, advocating a "starvation method of treatment" in the class of cases giving the largest death rate, reported upon his last one thousand appendicitis operations, with a death rate of two and one-fifth per cent., and since that time I have added a part of Dr. Ochsner's treatment, but prefer to do a five or ten-minute operation in the class of cases in which he would wait for the infection to become localized.

The question of removing normal appendices when they are at hand in the course of other operative work is one that I have never favored, on the ground that removal of the normal appendix delayed the operation and added a trifle of danger. Leave the appendix alone until it is infected, and then lose no time in having it inspected. This has always been my ground, and the idea that I ever favored removal of normal appendices must have been a reductio ad absurdum from statistics.

In 1902, acting from experience, and upheld by the statistics of Dr. John G. Clark in pyosalpinx work, I began to close the abdomen without drainage in appendicitis cases in which considerable pus and other débris had been left in the peritoneal cavity. The object in closing completely was to get a stronger abdominal wall and to get the patients out of bed sooner. The practice was based upon belief in the power of the natural resistance factors of the patient to dispose of such material by way of the peritoneal lymphatics.

As a result of the practice it was noted that primary union would occur in about half of the cases, but the patients would carry a temperature ranging up to 100° F., for days or even weeks after they were up and about. In some of the cases secondary abscess would form, but it always pointed at the incision, so no harm was done. In several cases in which primary union of the muscles of the abdomen was obtained, the adipose layer became infected and showed remarkable tardiness in granulating after the skin wound had been reopened. As a result of this experience I have gone back to the method of using a cigarette drain in all cases in which pus or septic débris have been left in the peritoneal cavity, but the wound is closed without drainage in cases in which gangrene and pus occur within the peritoneal coat of the appendix.

The question about the time for operating in cases of appendicitis is one that has had some fluctuations. The dictum which I promulgated about 1890, "Operate as soon as the diagnosis of appendicitis is made," aroused a storm of opposition. It was intended for a rule which would carry enough exceptions for its proving. In cases of acute progressing appendicitis I was sometimes persuaded to wait until a business man of large affairs could consult with his lawyers and get a business of millions into such form that others could manage it for awhile. Sometimes relatives of a school boy would telegraph us to wait until they could get to his bedside in a day or two. Occasionally I would be overbalanced in consultation with men whose opinions were highly respected. The results of such waiting have pointed straight back to the dictum.

In the class of cases in which the patient is suffering from the symptoms that go with involution of the appendix we may safely leave the matter to the decision of the patient, after stating the case clearly to him, and he may be allowed to assume the responsibility of saying when operation should be done.

In cases of acute appendicitis that are out of reach of competent surgical services, the patient is much safer under ice, opium, and starvation treatment than he would be under the kindest hands that attempted to render untrained surgical services.

In the patients who are certainly better on the day when we first see them than they were on the previous day, a question arises that has not as yet been settled—the only appendicitis question remaining on which I am uncomfortable. If we attempt to carry out the dictum we shall operate upon some patients who would do better if we waited for a month or two. On the other hand some of these convalescing patients spring a surprise upon us at midnight, just as we are taking the train for Chicago, and when we are not prepared for the emergency work required in sudden exacerbation of infection. I have had various views about individual cases in which the patients were convalescing, but have been made to feel that bacteria have ways of their own that are manifested without warning. In patients who were sent to me in the interval between

attacks, but with a clear history of appendicitis reported by competent physicians, I formerly believed that it was best to remove the appendices. My views on this point have changed, and it now seems best to operate only when on palpation the appendix is found to be the definite seat of chronic infection, or of adhesions which cause symptoms. The reason for this change of view is because some of the quiet interval appendices were found to have lost their inner coats, and there was no danger of further infection. The question is one, however, which rests entirely upon accurate palpation by satisfactory method.

TOXEMIA OF INTESTINAL ORIGIN AS A CONDITION PREDISPOSING TO MINOR INFECTIONS.

By HARRIS A. HOUGHTON, M.D.,
NEW YORK.

FELLOW OF THE NEW YORK ACADEMY OF MEDICINE; ASSISTANT SURGEON, THIRD DIVISION, BELLEVUE HOSPITAL, O. P. D.

Successful inoculation of living tissue with pyogenic organisms requires the coöperation of certain well-recognized factors. Broadly speaking, they may be said to be (1) a "vital decrease" to such an extent that normal resistance to the infecting agent is impaired, and (2) the actual presence of bacteria in sufficient numbers and of sufficient virulence to overcome the resistance offered. Both are essential.

The prevailing conception of the term "decrease in vitality" and the causes operative in its production is sufficiently clear in chronic toxemias. With contracting kidney, diabetes, or even in a prolonged lithemia, it is not difficult to picture retention of substances foreign to normal body economy, resulting in disturbed metabolism and the neutralization of Ehrlich's receptors. Here the conditions are admittedly perfect for the easy introduction and rapid development of sepsis. Hence, in major toxemias, we are usually able to uncover the etiology. Each succeeding decade witnesses the development of new methods of examination with more careful workmanship. As a consequence the demarking line between idiopathic vital decrease or the state of being "run down" on the one hand, and actual disease on the other, is constantly shifting in that direction alike more satisfactory to patients and practitioner.

There is, however, a wide difference between actual perfect health, and a condition wherein there may be no symptoms, but simply a decrease in vitality to such an extent that infections find a fertile field. It seems that nature provides for the normal man a leeway of great breadth, wherein his vital processes, inappreciable to any method of examination yet devised, may ebb and flow in response to varying adverse or favorable conditions. Quite as elusive are the numerous causes of these fluctuations. Unless there are obvious organic lesions, "going behind the returns" on the appearance of minor infections terminates in cleaning out the bowels and in the exhibition of iron in tonic form. This is pure empiric medicine, sometimes accomplishing the result, often not. Other conditions such as environment, adulterated food, and possible tubercular foci escape notice.

In the hope that suggestion may evolve knowledge, the following thirty cases of minor infections are reported as the patients presented themselves for treatment at Bellevue Hospital dispensary and in private practice.

Case I.—J. B., a cook, born in England, æt. 35. Father died of consumption and mother of Bright's disease. Previous history included major children's diseases. Since her twentieth year she had had many pelvic operations, and an appendectomy. She presented for treatment a carbuncle on the right shoulder about the size of a silver dollar. She also had a boil on the nose. This was the second carbuncle in four months. The urine contained indican in moderate degree and sugar.

Case II.—F. C., a laborer, æt. 59. Parental history unknown. Previous history included two attacks of pneumonia, one of typhoid fever, minor children's diseases, gonorrhea and constipation. For some time he had been losing weight. One week previous to treatment a carbuncle came "of itself" on the back between the shoulders. There was no albumin or indican, but a marked sugar reaction.

But little comment is needed on these two cases, for acetonemia is notoriously a forerunner of minor infections. Vitality often becomes so depressed that bacterial invasion is not essential to cause molecular or organic death. They are presented as illustrative of a type, and because they occurred in the course of the investigation. Another similar case follows:

Case III.—J. U., a cigarmaker, æt. 41.—Parental history was negative. His previous history included syphilis. A week previously a pimple appeared on the back of the neck. This degenerated into a boil. On questioning, it was discovered that he had had repeated attacks of tonsilitis during the previous four months and that he had been losing weight. There was well marked dullness on percussion in the left apex, and examination of the sputum showed tubercle bacilli. The urine was negative as to indican.

The sequence of events here is obvious. Chronic tuberculous toxemia may certainly be considered a vital depressant.

Case IV.—W. D., æt. 24, a builder, whose work was out-of-doors much of the time. Parental history was negative, excepting a slight tuberculous taint. His only variation from perfect health was the present sickness and a so-called "rectal abscess," the true nature of which could not be learned. This occurred two years previously. He ate fast and was occasionally constipated. Three years prior to his application for treatment his finger festered from a splinter, and he had been troubled with boils and two carbuncles since. He sometimes urinated twice a night. General physical examination was negative. He was healthy in appearance, and very muscular in build. Three boils situated on the finger and lower legs were opened and drained. Urine—Enormous excess of indican, occasionally a small hyaline and fine granular cast and numerous large calcium oxylate crystals. One week later the boils were healing, and the indican remained about the same in amount. One month later there had been no further infections, the symptoms noted above had disappeared and the indican gave but a slight reaction. Treatment here was directed toward lessening the amount of indican and the number of calcium oxylate crystals.

Case V.—T. M. B., æt. 22, a topographical engineer. He had a negative family and personal history, except that two months previously he graduated from college where he had studied very hard. He had always been more or less constipated. His general appearance was almost cachectic, with deep blue rings under the eyes. For three years he had been suffering from minor infections, and when I first saw him he had a carbuncle and three boils on the inner surface of the thigh. The urine was slightly albuminous, with occasional small hyaline and granular casts. Indican was present in great

excess. Calcium oxylate crystals were present in large numbers, and uric acid was deposited on standing. His treatment was similar to that in the previous case. During the two weeks following the first visit, sixteen boils were opened in various parts of the body. He was in bed two days of the time with a septic fever of slight degree. He continued treatment and diet for two months, during which time he grew gradually better, and his appearance improved. As I am writing this he tells me he was never in better health, and examination of his urine showed it to be practically free from indican.

Case VI.—T. H., æt. 15, a schoolboy with a slightly neurotic history on the mother's side. One year prior to his first visit he suffered from an attack of acute bronchitis, and following this at intervals he suffered with numerous boils. He exhibited two badly infected mosquito bites on his foot. General physical examination showed him to have a powerful muscular development for a boy of his age. His habits of life were exemplary. He was very fond of outdoor sports, and I know him to be a beautiful swimmer. His urine contained indican to great excess, and an occasional hyaline cast. No especial bowel treatment was instituted until a week later when he presented himself with a big carbuncle on the back between the shoulders. A month later his skin lesions had disappeared, and the indican was greatly diminished. One year later his urine was entirely free from indican, and he said that the previous winter had seen him in excellent general health.

These three cases from private practice are given together because bad habits, poor nourishment and unhygienic surroundings can be eliminated as causative factors. The patients were all accustomed to plenty of air and exercise, were moderate in diet, and yet, notwithstanding these facts, it is interesting to note that in two cases there was evidence of suboxydation in the urine. It will be noted that in the following series the infections occurred in laboring men accustomed to air and exercise, though in every case it was impossible to ascertain the character of their environments.

Case VII.—W. T. S., æt. 29, a boilermaker. His parental history and the history of childhood were unknown. He had pneumonia and pleuritis at 14. No lung symptoms since that time. Two days before he sought medical aid a carbuncle appeared on the right buttock. The urine contained a great excess of indican, a trace of albumin (by Esbach's test) and no sugar.

Case VIII.—J. A. C., a motorman, æt. 32. His parental and previous history was negative. For two months he had been troubled with various minor infections, including a suppuration under the thumbnail from a splinter. He was treated for a boil on the back of the neck near the hair line. Urine showed moderate indican excess and calcium oxalate crystals.

Case IX.—Charles P., æt. 38, a laborer. Parental history included tuberculosis. Previous history of typhoid at 10, following which he had been constipated. For a year previous to application for treatment he had been suffering from a train of small infections, including a felon on the index finger of the right hand, a carbuncle on the buttock, and also numerous boils. He was treated for a rapidly enlarging boil on the back of the neck. The urine was tested and indican in enormous excess was found. No albumin or sugar.

Case X.—P. O'B., aet. 43, a laborer. Parental and family history was unknown. History of syphilis some years previously. One week prior to admission a beam fell on his left leg, causing an abrasion on the calf. This had entirely healed, but above and externally were two boils. The urine contained a moderate degree of indican, but no sugar or albumin.

Case XI.—D. A. F., a driver, æt. 39. Parental and previous history negative. For one week he suffered from a felon, index finger of the left hand. Now he also shows a cellulitis on the dorsum of the hand and a lymphangitis of the forearm. The urine contained a trace of albumin (by Esbach), no sugar and a moderate excess of indican. No secondary objective symptoms of nephritis.

Case XII.—H. McK., æt. 16. Parents living and well. Previous history negative except for minor children's diseases. He was constipated. He presented for treatment a very painful and acute paronychia on the index finger of the right hand. The first joint was also involved. The urine was negative as to albumin and sugar, but the indican was very excessive. The wound healed slowly, and the bone of the terminal phalynx sloughed out.

Case XIII.—J. C., a stonemason, æt. 35. Parental history indicated a tubercular tendency. Previous history included an attack of facial erysipelas. He was constipated and drank to excess. The thumb of the right hand was injured by a tool, causing an abrasion of the skin. This became infected and four boils broke out on the arm above. The urine was negative except for a moderate excess of indican.

Case XIV.—W. R., a driver, æt. 23. Family history negative. Previous history of constipation and pneumonia. One week before admission he had a left axillary abscess opened at Gouverneur Hospital. This was slowly healing. He ran a splinter beneath the nail of the index finger on the right hand, and this promptly festered. Later a string of boils appeared on his forearm. The urine contained indican in great excess.

Case XV.—F. S., æt. 25, and a laborer. Previous history unobtainable, as he spoke no English. He had a burn of the second degree on the left hand. This healed slowly, became infected, and was repeatedly dressed for a month, when five small boils appeared on the arm above the burn. The urine showed indican in moderate excess. He also gave evidence of being a heavy drinker.

Case XVI.—J. S. S., an ironworker, æt. 24. Parental history negative, and previous history of children's diseases and constipation. Drinks much beer. During the previous month he had had three boils on his right forearm. He presented himself with a burn from an elevated third rail. This became infected and healed slowly. While this was being dressed he developed two more boils. The urine was pale, with a marked indican reaction and otherwise was negative.

Case XVII.—H. E., a carpenter, æt. 28. Parental and personal history negative. Two days before I saw him a pimple appeared on the middle finger of the right hand. This was followed by an infective periostitis of the finger and cellulitis of the hand. Patient was a typical hardy mechanic, living in the country. The urine contained indican to moderate excess and an occasional calcium oxylate crystal.

The first and last of this series were country dwellers, and it may be presumed that the balance lived in tenements. One-half of them suffered from infections which undoubtedly had their port of entry at some point distant to the seat of manifestation.

Case XVIII.—Clara F., a typical east side girl, aged sixteen. She was a bookbinder and worked in

a loft where light and air are considered unnecessary. There was tuberculosis in the family history, and her personal history included asthma and malaria. She had been feeling unusually well, however, for some time. She had two boils on the shoulder which appeared without apparent cause. Urine highly concentrated, no albumin or sugar, but the amount of indican was increased. This case is classified by itself because there was evidently bad environment and lack of nutrition involved.

Case XIX.—C. O., æt. 42, a driver. Parental history included cancer. Previous history negative. Good habits, but an excessive meat eater. He smoked a pipe often and had a suspicious lip ulceration, size of a half-pea. Two boils appeared between the shoulder blades four days before he presented himself at the clinic. The urine contained a trace of albumin, was of low specific gravity, no sugar and marked indican reaction. He had no secondary objective symptoms of contracting kidney and the blood pressure (Janeway, 12 cm. cuff) registered systolic, 160 mm. The lip ulceration demanded attention, and I have been unable to learn the subsequent history of the case.

Case XX.—W. R., a driver, æt. 23. Parental history negative. His personal history included a slight attack of pneumonia three years previously. One week prior to admission he had a left axillary abscess opened and drained. He came to the clinic to have three boils along the left forearm treated. The urine showed a trace of albumin (accounted for by a history of sexual excess and spermatorrhea), no sugar and a very excessive indican reaction. Another possible cause reveals itself here in the sexual history.

Case XXI.—J. McD., æt. 46, a bank cleaner. Parental history negative. He drinks freely. He had been a sufferer from headaches for a number of years, and from his appearance it was thought that they were due to refractive eye errors. He was constipated and a heavy meat eater. Two weeks prior to admission he had a number of boils and was suffering from a large boil on the calf of the leg. The indican reaction showed the presence of ethereal sulphates in great excess; no traces of albumin or sugar.

Case XXII.—C. B., æt. 32, a bottler. Parental history included rheumatism and Bright's disease. Previous history negative except occasional periods of constipation. He presented himself with a boil on the right cheek. The urine contained indican only in moderate excess.

Case XXIII.—H. K., a sculptor, German, æt. 57. The parental and personal histories were uneventful. He presented for treatment a boil on the right hand. He was a meat eater. The urine gave a reaction for indican in excess.

Case XXIV.—S. McG., an electrician, æt. 23. Family and previous histories negative. He had a carbuncle on the back of the neck the size of a silver dollar and four days old. The urine gave a slight reaction for albumin, a very heavy indican reaction, and contained occasional casts, hyaline in character.

Case XXV.—F. K. G., a buttonmaker, æt. 28. Parental history included rheumatism. A brother died of tuberculosis. Personal history was negative except that he was "never well" when a boy. He exhibited a fluctuating mass under the right arm. This was opened, and two ounces of pus oozed out. The urine gave no reactions for albumin and sugar and presented a large content of indican.

Case XXVI.—J. T., æt. 32, a cook. Parental history negative. He had a brother die of heart disease induced by rheumatism. Previous history included scarlet fever at five, from which later developed a mastoiditis. Operation at seven years of age which was in every way successful. He was suffering from a felon. This was opened and two days later the terminal phalynx sloughed out. The urine was negative except for a moderate indican reaction.

Case XXVII.—M. C., æt. 38, a cooper. Mother died of pulmonary tuberculosis. Never sick before, and was a drinker. Bowels regular, and he felt well. He had on his right shoulder a carbuncle which had lasted for over a week. The urine showed no albumin or sugar, but contained indican in great excess.

Case XXVIII.—L. U., a crockery packer of the Jewish race, æt. 45. Mother died of consumption. Always healthy. Occasional constipation. Nine months previously he was operated upon for stricture of the urethra and varicocele. He had had a paronychia for four days. Boils on face and neck within a month. The indican reaction was greatly increased.

Case XXIX.—T. L., æt. 39, a German piano polisher. He drank moderately. There was a cellulitis starting from an abrasion on the dorsum of the right hand. He also had an infected spot over the canthus of the right eye. The indicanuria was marked; no sugar or albumin was present.

Case XXX.—T. G., æt. 17, a printer. Parental and previous history negative. One week prior to admission a pimple appeared on the right lower jaw and rapidly developed into a large boil. There was a moderate increase in indican, but no albumin or sugar.

In obtaining these histories and making the necessary physical and urinary examinations, care was exercised to exclude other morbid conditions. The question, for instance, as to the use of meats and the habits of the bowels was asked, and if not especially mentioned as present, such factors may safely be excluded.

Whole number of cases examined	30
Number presenting glycosuria	1
Number presenting glycosuria and indicanuria	1
Number presenting tuberculosis	1
Number presenting excess of indican in the urine (contracting kidney being excluded as far as possible)	27

Leaving the main conclusion to be discussed later it may be well to review the evidence presented. There are undoubtedly many causes not specifically mentioned. Unhygienic environment, poor nutrition (as was particularly well marked in one instance), food adulteration and its bad preparation, and alcohol, all may be said to have played their part. It would be difficult to collect thirty cases in which these causes could be entirely eliminated. We can also pass organic or systemic diseases, three cases of which were encountered. A coexisting condition of lithemia and suboxidation, as evidenced by urinary examination, was met in a goodly percentage, and at least in two instances (Cases IV. and V.) when it was least to be expected. There were no histories of hereditary tendency to gout or rheumatism in these two cases, and from personal knowledge I can say that their habits and lives are all that is to be desired.

The extent to which vital processes were interrupted was aptly illustrated in another way. It may be supposed that in a healthy individual, a wound will either heal by first intention or with but little local reaction. In a goodly percentage of our cases, however, there were reproductions of the infections either in close proximity to the initial lesion, or at distant points. Initial wounds also healed slug-

gishly. But the one striking condition present in every case (except two, referable to tuberculosis and diabetes) was that form of toxemia which has its etiology in the small intestine and its principal index in the urine, viz. autointoxication. It was often complicated with other morbid conditions. But a sufficiently large number of cases remain in which it was apparently the main factor. We are then in a position to make a tentative conclusion, subject to future revision:

Conclusion.—In many cases of vital decrease, manifested objectively by minor septic infections, toxemia of intestinal origin may be regarded as the predisposing cause.

It may readily be seen that the direction toward which this conclusion points is very far reaching. It suggests for instance an explanation of the problem met by the surgeon: given two patients of apparently similar vitality, the same operation and a fixity of technique, why is it that one will promptly recover and the other perhaps either take longer to recuperate or die of sepsis? In the domain of infectious medical diseases, why is it that one person contracts typhoid fever and another does not? This leads us, of course, into that fascinating field of study comprised within the limits of natural immunity for which the dawn of knowledge is just beginning. But the train of thought is certainly apparent.

The practical application of the conclusion means attention to the proteid fermentation taking place in the bowel, particularly in those cases in which the urine presents a large amount of indican. It is not sufficient simply to produce evacuation of the bowels. The indicanuria must be treated by diet and other procedures looking toward its complete cessation. This will undoubtedly completely cure many troublesome cases of recurring minor infections.

Bayside L. I.

RESPONSIBILITY IN MENTAL DEFORMITY.

By JAMES WEIR, Jr., M D.,

OWENSBORO, KY.

The law recognizes certain degrees of responsibility in the mentally diseased; yet, strange to say, with but a few exceptions, it fails to take cognizance of the sociolegal status of the mentally deformed.

Moral philosophy, as enunciated from the pulpits of our churches, is founded on *quasi* Socratic premises; on the assumption that mind is an "essence flowing from divinity," and that its origin is not, *per se*, physical in character. This faulty concept of the nature of the mental organism is to blame for the peculiar legal situation outlined in the first paragraph of this paper.

That there can be physical deformity without physical disease no one will dispute; and that deformity is confined, *in toto*, to the macroscopic and miscroscopic anatomy of the body the psychologists and alienists of the present era must emphatically deny.

Mind cannot be seen with the microscope, nor can it be viewed with the naked, unaided eye; yet clinical evidence declares, beyond peradventure, that it has a physical basis; that it is merely a resultant of nerve cell action. And just as any other function of the physical organism may be diseased, perverted or deformed, the mind itself may become the subject of lesions and deformities.

It is beyond the scope of a paper like this to discuss all of the multiple and varied abnormalities of the mind (be it understood deformity is meant when the word abnormality is used), which are to be observed in a study of the strange, wonderful, often disgusting and bestial perversions of the psychical being which daily meet the student who follows the devious paths of psychiatry.

The undoubted kinsmanship of the brute and human is brought plainly to the view by certain of these mental habitudes, and that strange yet most true of all the tenets of evolution, the law of atavism, is but emphasized and made most evident. The doctrine of mental heredity, that most abstruse and most frequently debated of all psychological questions, is strengthened, in fact, made almost undeniable by data in its favor.

The body-birth of psychos, the "parting of the ways," not only of the ancient medieval philosophers, but also of the classicists of to-day, also drags down the scale in its own favor when it is weighed against the evidences of an immaterial, extra-physical or spiritual origin.

Thought must be, necessarily, a conservation of energy. Helmholtz, in one of his university lectures, announces this almost in the shape of a dictum, a doctrine not to be disputed. Recent experiments demonstrate the fact that there is an expenditure of physical dynamics in every act of conscious or unconscious ideation. Baldwin, Loeb, Dana, and many others have shown this both in their laboratory work and in their public demonstrations. Hence, there is not one authority of any weight throughout the entire scientific world who will deny the physical basis of the mind.

We cannot tell in so many words what electricity, what heat, what light, and what dozens of other natural phenomena are; we only know that they are forms of energy. Neither can we enter into the details which constitute the thousand and one conservations, resultants of these energies. Our finite thought can only go so far and no farther. Just so with mind; we know that it must be a conservation of energy—a resultant of nerve cell action in which energy undergoes transmutation and makes its appearance in other shapes.

Mind and thought (ideation, ratiocination), are not analogous, and the reader must bear this in mind throughout this paper. There can be mind without thought, but no thought can be formulated without the existence of mind.

As we study the question and tabulate the data, it becomes more and more patent that mind and all that its multifarious manifestations imply, being founded from the very beginning on a physical basis, is, like any other bodily function, subject to deformities.

We are aware of the fact (and do not question it for an instant), that deformities (perversions, etc.), of the senses, physical functions differing from the mental functions only in kind and method of appreciation, exist; therefore, we have no right, logical or otherwise, to deny deformity in the case of the mind. Especially must this be allowed when we remember that mind itself, conscious and unconscious, is based upon the senses.

The law in dealing with the mentally deformed uses statutes in most of the States which are framed solely on responsibility in mental disease; in no State does the idea of responsibility in mental deformity enter into the treatment of the psychically deformed in any law as now written in which the mental pervert is recognized as such.

It is true that in some States legislators seem to have had some inkling as to the importance of this question and have, in a measure, vaguely recognized the existence of a certain class of mental abnormalities; the establishment of reformatories points to

this. Yet, even in these states (far in advance of their sister commonwealths as they are), the real grain of wheat in the bushel of chaff has not yet been discovered; the ancient "essence of divinity" idea of mind still clings to legislators and clogs their footsteps with its weight of ethical paradoxes in their search for it, and blinds their eyes to its presence, although it lies in plain view! Huxley's "Mosaic fence with its comminatory sign-board: 'No Thoroughfare!'" still stands in the path and blocks the way of many a seeker after truth!

Owing to its limitations, the law is forced to use its statutes, framed solely as to responsibility in mental disease, when dealing with mental deformities. This is wholly due to the faulty concepts of the origin of the psychical organism as enumerated above.

Thus, congenital imbecility, which is purely a mental deformity, in nine case out of ten, presenting no physical lesions whatever, is recognized by the law; yet, is classed, legally, among the insanities. So, too, are the many forms of retarded and imperfect intellection and phychical defects.

Though the congenital imbecile, as far as physical functions are concerned, may present no abnormalities, yet, in the vast majority of cases he "shadows forth in face and form the semblance of a mind unbalanced and unstrung"; his mental deformity is reflected in pendulous lip, unsteady tongue, expressionless eye, titubating gait, and ill-formed torso.

The congenital criminal, "the savage dwelling in the midst of civilization," likewise indicates by certain physical stigmata the deformity existing in his psychical organism.

No one who has made a study of criminology and who is willing to accept the testimony of exact data, and who will give to the question an unbiased judgment, will deny the existence of those stigmata, and that they form a type as fixed as any other type to be found throughout all nature. The mental habitudes of the congenital criminal also emphasize the fact that he is a man apart and, like Caliban, "a freckled whelp, hag-born," as far as normal ethics are concerned. Some years ago, in the *Scientific American*, the MEDICAL RECORD, and the *Century*, I presented my personal evidence as to the existence of the congenital criminal, and described in detail the physical and psychical abnormalities which declared him to be, as far as the civilized, normal man is concerned, a being wholly *sui generis*.

These conclusions and deductions were supported by photographs and drawings made by myself which were gathered "in the field," and not from books. To Lombroso, Ferri, Ellis, Krafft-Ebing, and others I owe thanks for directing my researches towards this branch of psychiatry, and to them I cheerfully give primogeniture as far as many of these dicta are concerned.

Mr. Howells has boldly announced it to be a fact that Lombroso and his school generally succeed in finding what they start out to find. In writing thus, the gifted novelist shows, at once, that he is venturing into unknown territory. For many years before Lombroso and his so-called school came into existence, the congenital criminal had been noted and described, and his status in the social régime of civilized life definitely pointed out. Ellis and other distinguished English authors call attention to this fact in works, which, to the student of psychiatry, are as familiar as the alphabet. So that, Mr. Howells, the critic of Lombroso and his methods, had abundant data in his own language as to the standing of this question and its merits, even were he ignorant of foreign tongues.

The born criminal cannot be ignored in this day of modern psychology when the warfare between good and evil is recognized to be purely a personal matter as far as it touches the well-being of the antisocialist in his relations with his fellow man. This applies, of course, to the attitude in which the delinquent regards himself when he compares his status with that of the law-abiding man.

"The devil when sick a monk would be, etc.," does not apply to him in its ethical sense; his deformed psychical organism renders him a devil, sick or well; there is no monk in his mental habitudes, though he may robe himself in the soutane of a priest to further his own ends. Mentally, he is incapable, owing to his psychical obliquity, of looking at social law from the standpoint of the normal, law-abiding man.

Of course, I have reference to the congenital antisocialist, to the recidivist; the occasional criminal, the criminal through opportunity, does not enter into this study of the question except casually.

Now, in some of the eastern states, as well as some of the middle southern states, the physical aspect of criminology has been recognized and studied in a slight degree, though the magnitude and very great importance of the subject are only beginning to fully penetrate the veneer of the clerically artificial judgment of our law-makers.

Some few, very few, indeed, of the originators of state law have refused to assign to the devil the importance which his antagonists readily yield him; these few legalists disregard his Satanic majesty and yield first place to the unchangeable dicta of Natural Law! They recognize the physical basis of *psychos* and build their laws accordingly.

They are aware of the fact that, through the instrumentality of operation and brace, a club foot, where treated early in life, may be, and is, in the vast majority of cases, cured and the foot rendered useful and no longer a deformity. Just so with the criminal; they have become aware of the fact that the psychos of the youthful criminal, if taken in time and properly treated, will respond readily to that treatment, and that, comparatively speaking, a useless and expensive citizen may become, in the end, a desirable member of society.

I do not say that all of our advanced law-makers are aware of the physical forces which bring about these changes; I am inclined to believe that the majority of them think that they are warring against a personal devil, and that the battle is a spiritual instead of a physical one. The end, however, justifies the means, and, as that end is reformatory institutions, let them fight under whatsoever banner they may choose.

Whenever the kleptomaniac is mentioned in general society, a covert smile crosses the face of the wiseacre of the company; he is too wise to be "taken in"; in his opinion it is simply "a case of stealing." Yet, the kleptomaniac is truly a victim of psychical deformity and should be treated as such. Unfortunately the law is so framed that he is either classed among the insane, or, his mental status unrecognized, he is judged to be a criminal and treated accordingly.

Spencer, Huxley, Darwin, Wallace, Reclus, Haeckle, Wolfe, Ellis, and hundreds of others have preached the doctrine of evolution and have demonstrated that the law of atavism (the return to ancestral conditions), is the truest tenet of this all-powerful dictum of Natural Law; yet, the world at large fails to recognize the vast importance of this factor in the law of Universal Progress. It is willing to believe that the world is growing better, yet unwilling to grant that failures make successes doubly sure. The average citizen is prone to judge by appearances; he does not look below the surface and is satisfied with the reflection of his own, individual mirror.

A Universal Picture Machine, showing "living pictures" of civilization from its inception to the present time is an impossibility; yet any man who so wills can sit in a public library and picture forth the history of his ancestor from the time of the cave dwellers to the present moment.

Scientists tell us that there was a time in the history of man, when men held all things in common; "mine and thine were unknown, and immediate possession was the only law. The dwelling, the boat, the spear, the cooking pot, even the apron of leaves, and the wife, were communal; there was no mine and thine."

Owing to psychical deformity the kleptomaniac reverts to those ancient times; ethically he recognizes no difference between *meum* and *tuum*, and becomes, in this respect, the autotype of his savage ancestor. Modern law declares him insane; modern thought declares him psychically deformed. This single instance of mental deformity (were there not dozens of others!), where disease and abnormality, *sine morbo*, are not differentiated, but which are held to be the same and are treated as such, is enough to make the modern law-maker cry "Halt! whither am I drifting!" Of course, kleptomania may exist as one of the symptoms of mental disease; it is then pseudokleptomania. True kleptomania, as I understand it, is *sine morbo*—"without disease."

In the brief space of a magazine article it will be impossible to call attention to all of the mental deformities which force themselves into the view of the student of sociology and psychiatry; their name is legion. Yet, the psychosexual deformities play such a prominent part that no essay on this important subject would be complete without at least a short outline of some of the most frequent of these aberrances.

Alice Mitchell to-day drags out a weary existence in a madhouse simply because her psychical hermaphroditism was not recognized early in life and treated as such. The law, in her case, is cruelly and unjustly punitive, because it declares her insane when she is suffering from a psychical deformity which could have been cured had it been recognized early in life and treated as such.

"Jack the Ripper" and his thousand and one prototypes would have never materialized had the fact of their psychical deformity been recognized early in life and treated as such. Of course, many of these mental perversions are directly due to disease; but far the larger number are deformities, pure and simple, which can be treated and cured.

Was J. J. Rousseau mentally diseased? was Sir Walter Scott, or our own Poe? There was absolutely no evidence of disease in the minds of either of these men; yet there was unmistakable obliquity. Was Guiteau sane? I take it that almost every alienist of any note will declare his belief in his sanity, yet all will say that he had a "twist in his mind."

There is hardly a day that passes in which the newspapers fail to chronicle the imprisonment, either in penitentiary or lunatic asylum, of some one mentally deformed. As the law now stands it cannot do otherwise.

"WAYBLAND."

Alleged Increase of Pneumonia.—An elaborate series of graphic tables is presented by J. S. Fulton, whose conclusions are as follows: (1) The returned mortality of the United States for ages between 15 and 60 during the past twenty years shows a diminishing mortality from the class of respiratory diseases commonly returned as pneumonia. Of the pneumonias occurring in this age period a large majority are true lobar pneumonia. Fifty-eight and a half per cent. of the population of the United States, and 66.5 per cent. of the population of cities are between the ages of 15 and 60. The incidence of lobar pneumonia on a major part of the population is therefore diminishing. (2) The return mortality of the United States, for ages above 60, indicate that the mortality from the class of respiratory diseases commonly returned as pneumonia has increased from 21.9 per cent. to 22.6 per cent. in ten years, the population at the same age in the same period having increased from 6.2 to 6.6 per cent. The urban mortality for the same age has grown in ten years from 16.1 to 19.5 and has been accompanied by an increase of population in that age period laterally from 5.23 to 5.27 per cent. Several pathologic conditions added to the group of pneumonias, and not provided for in statistics, are included in the returned mortality of pneumonia for ages above 60. For six per cent. of our total population lobar pneumonia may have increased in the past ten years, though satisfactory evidence of an increase has not been offered. (3) The return mortality of the United States for ages under 15 (about one-third of the total population) shows an apparent rise of mortality for the group of respiratory diseases commonly classed as pneumonia. The acute respiratory diseases of children were in former years commonly mistaken for affections of the nervous system. Year by year for thirty years increasing numbers of deaths formerly found in the indefinite accounts, and in the class of nervous diseases, have been transferred to the class of respiratory diseases and especially to the pneumonia account. Of the mortality recorded as due to pneumonia under the age of 15 years, not more than 10 per cent. is due to lobar pneumonia. A small though considerable incidence of lobar pneumonia in children under the age of 5 has come into view of late years, but there is no evidence that lobar pneumonia has increased in this age period. The remaining 90 per cent. of the recorded mortality ascribed to pneumonia includes the conglomerate group of bronchopneumoias, nearly all of which are secondary or complicating causes of death, and should be referred in the mortality tables to the primary causes of death. (4) Since 1890 a new cause of infantile mortality has come into view, an acute respiratory infection, attacking infants of 2 years old and under, commonly returned under the diagnosis of pneumonia, sometimes returned as due to a disease of the nervous system, and probably due to influenza. (5) The mortality registration of American cities is in general very poor. The crude rates and ratios offered by certain cities as evidence of a rising pneumonia mortality are inconsistent with the mortality statements concerning other causes of death, and with the characteristics of the populations concerned. They represent a perversion of statistics which must eventually bring discredit on American mortality registration.—*Journal of American Medical Association.*

Gout.—E. Schmoll offers the following as his conception of gout: In gout the uric acid is produced not only by oxidation of purin bases, but by synthesis; this synthesized uric acid therefore has not at its disposal the thymic acid necessary for its solution in the blood. This is why we can detect uric acid in the serum. If the formation of the synthetic uric acid increases for any reason the serum becomes saturated, and as no thymic acid prevents its precipitation it is deposited as tophi in the joints. He explains some difficulties of this theory and gives the results of his experiments with the thymic acid treatment. The excretion of uric acid is constantly increased during the medication and gouty attacks cease to appear, the swelling goes down and, in some cases, entirely disappears. The dose is about one-quarter of a grain three or four times a day, and is given after meals to avoid gastric disturbance. Larger doses, three or four grains in twenty-four hours, may cause local inflammatory reaction. He does not claim to cure gout in this way, but simply to neutralize the primary metabolic disturbance revealing itself by the synthetic formation of uric acid.—*Journal of the American Medical Association.*

MEDICAL RECORD.

A Weekly Journal of Medicine and Surgery.

THOMAS L. STEDMAN, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 FIFTH AVENUE.

New York, May 27, 1905.

VALE OSLER.

DR. WILLIAM OSLER sailed for New York on Friday morning of last week, to enter upon his last professorial charge as Regius Professor of Medicine at Oxford, and his going is a cause of profound regret to his American confrères. Although a British subject and never relinquishing the allegiance to the English throne which he owed by virtue of his Canadian birth, he gave the best thought of his ripest years to the cause of medicine and especially of medical education in this country. The Johns Hopkins Hospital and the Medical School of Johns Hopkins University owe to him more than to any other one man the high rank which they hold among similar institutions throughout the world, and so thoroughly identified had he become with American medicine that the announcement of his acceptance of the call to Oxford came as a rude shock to his colleagues here, who had almost forgotten that he was not really theirs, but was only borrowed.

For nearly twenty years Dr. Osler has been one of the most conspicuous men of his profession in the United States, and unquestionably the most popular His preeminence rested upon his unusual literary abilities, his geniality, and his lovable personal character. As a medical practitioner and consultant he had many superiors, but as a medical writer he was facile princeps. There are others of his profession who rank higher in the literary world, for into the field of general literature he made few incursions, but in his ability to clothe the dry facts of medicine in a fascinating literary style which compel attention he has no equal. He is peculiarly happy in his addresses before graduating classes and medical assemblies, and there are few volumes of medicoliterary essays more entertaining than the collection recently published under the title of "Æquanimitas." The charm of his writings is in the style perhaps more than in the substance, and his serious contributions to the advancement of medical science have been few, for though a student and investigator, his forte has lain rather in the presentation of medical truths than in the discovery of new facts.

He did not begin to write until he was forty years old and has thus furnished in his own life abundant disproof of his contention that a man's best work is done before he has reached that age. If one were to accept the logical conclusion of his now famous lecture, Oxford could hardly be congratulated upon her possession of the fag end of his life of usefulness. But no one but Osler himself would dream of setting a term to his active and creative life. He may count his years as fifty-six, but his mind and body are still those of a vigorous youth, and to any one who saw him at the farewell dinner in this city a few weeks ago or who heard him speak at the Tuberculosis Congress in Washington last week the idea of his superannuation at the end of four years is unthinkable. That his sovereign may mark that period by the bestowal of merited honors upon his illustrious subject is most probable, and the event will be an occasion of joy to his American colleagues, but that he should be allowed so soon to retire from the Regius professorship and give himself over to an inactive life of contemplation and preparation for the end cannot be imagined. The annals of medicine nowhere contain such an example of presenility as that would furnish.

THE MENACE OF THE TRAVELING CONSUMPTIVE.

THE subject of the dangers resulting to the community as a whole from traveling consumptives has been dealt with frequently and exhaustively. The fact has been driven home that practically no effective precautions are taken to prevent a person suffering from pulmonary tuberculosis from disseminating the germs of the disease among his fellow passengers. Notwithstanding, however, the numerous warnings which have been uttered, little or nothing has been done by railroad or steamboat authorities to minimize the risk of spreading infection.

In the *Journal of the Association of Military Surgeons,* in May, 1905, Dr. John William Trask, Assistant Surgeon in the Public Health and Marine Hospital Service, writes concerning these dangers. He draws attention to the fact that there is a very large number of consumptives traveling in the Western States and territories, who by reason of the lack of adequate precautionary measures are a menace to the community at large, and he ventures the opinion that if as many consumptive individuals made use of the railroads in the East as in the West, proper legislation would have been demanded and enacted ere this.

There can be no doubt when persons suffering from pulmonary tuberculosis travel in trains, without knowing or caring how to protect their fellow passengers, that such trains must become badly infected. Dr. Trask points out that criminal carelessness is everywhere exhibited by consumptives, some erring through ignorance, while others are indifferent to the fact that they are ambulant foci of infection. Promiscuous expectoration is the gravest source of danger.

As to remedies for the existing condition of affairs, the author reiterates the suggestions in this direction which have been so freely scattered around during the past few years. So far, however, as advice concerning the control of consumption is concerned, we appear indeed to be a stiff-necked generation. The principal authorities on the disease have proclaimed loudly from the housetops the obvious means that must be taken to prevent the spread of tuberculosis, but the words of wisdom, as a rule, have fallen upon unheeding ears.

The truth would seem to be that an educational propaganda must be undertaken and continued by the medical profession until the general public thoroughly understand the facts of the situation. The cooperation of the medical profession and the people

at large must take place ere effective work can be done toward abolishing consumption. Dr. Trask shows that correct and early diagnosis of the disease is an essential feature of a successful campaign. Notification is a useful means of ascertaining how many consumptives there may be in a community and where they are.

With regard to preventing the spread of consumption by traveling sufferers from the malady Dr. Trask suggests many remedies. He holds that coaches should be furnished and upholstered far more plainly than is at present the case, and that each car might be disinfected with formaldehyde or sulphur dioxide at the end of each trip, or, if the car makes but short runs, two or three times a week. Common drinking cups at the water tanks should be abolished. On dining cars all dishes should be well scalded with boiling water in addition to the mechanical cleansing commonly termed washing. In sleeping cars, in addition to the freshly laundered linen, blankets which have been sterilized since last being used could be furnished.

All consumptives should be required to use sputum cups while on the train, the cups to be furnished by the trainmen and cleansed and sterilized when full free of charge. Lastly, the author recommends that all trains carrying passengers to and from the Southwest should be fitted with special compartments in which consumptives who cough and expectorate tc any extent can travel by themselves.

Whether it be possible entirely to exterminate consumption is more than doubtful. It may be taken as proven, however, that the spread of the disease can be very considerably narrowed by using ordinary common-sense precautions, and certainly railroad and steamboat authorities can effect much by adopting and enforcing certain regulations with regard to the conduct of traveling consumptives.

THE BENEFICENT DUST.

This is an age of rehabilitation. The Borgias have been whitewashed, and it has been shown that Nero, instead of being a vicious and licentious profligate, was on the whole an estimable character. And this rehabilitation process is being extended to inanimate things as well. Dust, either in the streets or in houses, has hitherto been regarded not only as distinctly unpleasant, but as highly dangerous to health, and the theory that the germs of many virulent diseases are contained in dust and carried by means of the wind to infect those susceptible, has been vigorously propagated. Indeed, it is a matter of popular belief that the commoner contagious diseases are disseminated through the agency of street dust.

Dr. J. J. Cassidy, member of the Provincial Board of Health of Ontario, has, however, recently written an article in the *Sanitary Journal* of that body, in which he deprecates the ventilation of these extreme views and holds that they are not justified by facts. He quotes at length from well-known authors, and summarizes as follows: The contention that tuberculosis is spread through the inhalation of bacilli-laden dust is true. It would not, however, be a safe conclusion that the street dust, wafted about in the open, contains the bacilli tuberculosis in a virulent condition. The evidence points rather the other way, viz., that this same dust parts with its virulence in proportion to its free exposure to air and sunlight.

Smallpox is conveyed from the sick to the healthy, or from one person to another, by (*a*) inoculation with either the blood or the contents of the eruption or the dissolved dry scabs; (*b*) proximity to a patient suffering from smallpox; (*c*) fomites. The distance to which the contagion of smallpox can be conveyed through the air is probably considerable, being, according to English data, from a half to three-quarters of a mile. Measles, scarlet fever, whooping-cough, diphtheria, and influenza are communicated from the sick to the healthy or from one person to another directly by the patient (through contact or sputum thrown into the air), or indirectly by bed-linen, body-linen, furniture, toys, etc., which have been used by the patient; but these diseases are not communicated to persons at a considerable distance, by being wafted through the air in dust.

Street dust, asserts Dr. Cassidy, is not, as is the general belief, a vehicle of the commoner contagious diseases, because it contains a large percentage of horse manure. Rather, judging from analysis of street dust, it acts as a ferment and has a strong disinfectant power on the sputa of scarlet fever, diphtheria, measles, whooping-cough, or influenza, and is capable of destroying instead of enhancing the virulence of these sputa.

The germs in the dust of a room from which sunlight is more or less excluded will retain their virulence for a considerable time, but those in the dust outside exposed to sunlight rapidly lose their virulence and cease to be infective.

The Treatment of Diphtheria.

In the *Practitioner* for April is published an article by Dr. J. T. C. Nash on the treatment of diphtheria. The writer lays especial stress on the necessity of treating diphtheria in its earliest stage; in fact, the whole trend of the paper is in this direction. In order to accomplish this disideratum, one of two things must be done: either the disease must be diagnosed early and treated or a suspected case must be treated. Now, it is more or less obvious that it is almost impossible always to diagnose correctly diphtheria in its early stages; other throat affections, follicular tonsillitis in particular, simulate it in many respects so closely that without a careful bacteriological examination it is extremely difficult to differentiate with exactitude between diphtheria and three or four maladies which attack the tonsils. Country practitioners and even many town medical men have not the means at hand for bacteriological examinations, and moreover such examinations are not in all cases conclusive, and in any event precious time is wasted. Dr. Nash therefore urges that whenever there is a suspicion of diphtheria the serum treatment should be adopted at once as a preventive measure. He says that, with our present-day knowledge that diphtheria is practically rendered non-fatal if treated with a suitable dose of diphtheria antitoxin on the first day of illness, it is almost criminal to defer serum treatment until a bacteriological examination has been made. He is of the opinion that 2,000 units should be administered, subcutaneously, directly there is a suspicion that the case might be one of diphtheria. The antitoxin should always be administered subcutaneously. Nash points out that diphtheria antitoxin belongs to the preventive more than to the curative medicines. The author is also a firm believer in the efficacy of strychnine in heroic doses in the treatment of diphtheria. He occasionally gives to children as much as 0.03 grm. (nearly ½ grain) in divided doses during several consecutive

days, followed by smaller doses for a subsequent considerable period. For the rhinitis, which is so frequent a complication of severe attacks of diphtheria, antiseptic douchings of the nasopharyngeal passages every four to six hours is recommended. Park advocates in this condition the use of bichloride of mercury 1-1,000 or a weak solution of hydrogen dioxide. If the latter is used, care must be exercised to secure as pure a product as possible, as if the hydrogen dioxide contains impurities, the mucous membrane of the nose and mouth will be injuriously affected. There can be no doubt that it is a question of the utmost importance for diphtheria to be treated in its early stage. Taken in time, diphtheria antitoxin will abort the disease in the majority of cases. The suggestion of Dr. Nash, that every suspected case should be treated with a generous dose of antitoxin, is undoubtedly good practice.

Nervous Asthma and Skin Diseases.

The question of the relation of skin eruptions to affections of the nervous system, is one that has long interested dermatologists and neurologists alike, and fresh contributions to the subject are constantly appearing in medical literature. One of the most recent is a paper read by Bayet before the Société Belge de Dermatologie et de Syphilis and published in the Bulletin of that Society (No. 3, 1904). The paper was an essay on the relationship some asthmatic affections bear to cutaneous outbreaks, and the following were Bayet's conclusions: (1) It is incontestable that, in certain cases, there may exist a very marked alternation between asthma and the cutaneous affections which accompany it. (2) In certain cases this alternation is observed only when the case is watched for over a considerable period. It is not immediate. The sudden disappearance of the dermatosis has no marked influence on the attack. It is noted that taken together the periods of inactivity in the cutaneous manifestations are accompanied by an aggravation of the respiratory symptoms. (3) In certain cases this alternation is not seen. (4) In others the exacerbations of asthma are accompanied by aggravation of the skin symptoms. It is probable too that there exist still other types of relationship between nervous asthma and the dermatoses which accompany it. (5) The relationships which bind asthma to dermatoses are not the same for the whole course of the disease. The alternation or balance may lose its distinctive character. At a given moment the two affections may simultaneously diminish. (6) The physician should treat all dermatoses in an asthmatic, and he is at liberty to cause a reappearance of the neurodermatitis if curing the skin affection brings about a too violent return of the asthma.

The Bad Effects of Surf Bathing.

The manner in which surf bathing is carried on at the fashionable seaside resorts of this country is by no means conducive to good health. Sea bathing in moderation is beneficial in a certain class of maladies, but excess is distinctly harmful. The *St. Louis Medical Review*, April 29, calls attention to this fact and quotes from an article by Dr. Philip Marvel, which appeared in the *Journal of the American Medical Association*, April 8, deprecating the mode of bathing at the Atlantic coast resorts. The writer holds that this kind of bathing does more harm than good, and urges physicians to warn patients of the dangers of too long immersions and of exposure in wet clothes on the sand. It is pointed out that an important feature in sea bathing is the impact of the waves on the body, to which may be added the thermic stimulation of the cold, the chemical irritation of the salt, and the mechanical effect of forced activity, all producing a combination of the stimulating influence of a brine bath at low temperature with that of a hydrotherapeutic procedure. These effects are admirable for stimulating functional activity in weakened conditions in which normal metabolism is inhibited or in which a condition of perverted nutrition exists, as in some functional disturbance of long standing. Sea bathing is contraindicated in weakening or loss of elasticity of the arteries, organic heart disease, recent rheumatism, cholelithiasis, acute gastrointestinal or febrile disease, or any condition in which the normal resistance is so reduced that it is necessary to guard the patient's forces.

News of the Week.

An Amendment to the Child Labor Law.—A bill amending the Child Labor law has been signed by Gov. Higgins. The bill aims to relieve a numerous class of children who are unable to produce evidence of their age required under the present law before an employment certificate can be issued, and who, in consequence, have been obliged to go back to school. The bill allows local boards of health to accept "other satisfactory evidence" where the evidence at present required (birth certificate, baptismal or religious records or passport) are not to be obtained and when it appears that the child is of the age required. This new evidence must be submitted to the Board of Health at one of its regular meetings and made a part of the minutes in each individual case by separate resolution.

A Tuberculosis Exhibition.—It is announced that the first American Tuberculosis Exhibition will be held in this city next November under the auspices of the National Association for the Study and Prevention of Tuberculosis, and of the Committee on the Prevention of Tuberculosis of the Charity Organization Society. The committee in charge, of which Dr. Lederle, former Commissioner of Health, is chairman, is looking for a large exhibition hall, centrally located, which, it is hoped, may be obtained without charge for a period of two weeks. The committee is also soliciting contributions sufficient to insure the undertaking against financial loss. In addition to exhibits intended to illustrate different phases of the tuberculosis problem, and especially the treatment of the disease, popular lectures will be delivered by specialists. Such exhibitions have been found of great value abroad in educating the masses, and it is to be hoped that the present project will meet with the support it deserves.

Quarrel Between School and Health Boards.—There is excitement in a town in Iowa regarding the diagnosis of a disease from which many of the children of the place are suffering. The State Board of Health has pronounced the disease scarlet fever, but the members of the local School Board and other intelligent citizens of the place dispute the diagnosis in true Russian peasant or Hindu style. Two physicians sent by the Board of Health to investigate the disease and who pronounced it scarlet fever were forced to get out of town under cover of the night owing to the threats of the enraged citizens. A local physician who agreed with them was hanged in effigy, and another who placed quarantine signs on several houses was threatened with violence, and the signs were torn down within ten minutes. The School Board asserts that it will prevent the fumigation of the school buildings by force if necessary. The State authorities have notified the superintendent to close the schools.

A Marine Biological Station.—Arrangements are now almost complete for the opening of a marine biological station at La Jolla, a suburb of San Diego, Cal., under the direction of Prof. William E. Ritter, of the University of California. The laboratory will take the place of the one that has been conducted by Prof. Ritter during the past year or two at Coronado Beach. The change of location has been made on account of the better facilities for obtaining specimens at La Jolla, where the forms of ocean life most desirable for study approach to within a short distance from the shore. This region is also considered the best for research work in the United States, the climatic conditions being such as to permit of continuous study, summer and winter.

Medical Colleges Consolidated.—The Kansas City Medical College and the Medico-Chirurgical College of Kansas City, Mo., have been consolidated and a faculty will be chosen from the combined schools to form the medical department of the Kansas State University. The Ensworth Medical College and the Central Medical College of St. Joseph have also consolidated, the new school to be known as the Ensworth Medical College.

Pediatric Hospital to be Opened.—A new children's hospital, situated on the grounds of the Cook County Hospital, Chicago, will be formally opened on May 23. The hospital is three stories high, has 20 wards, accommodates 150 patients, and occupies 147 by 43 feet of ground. It has isolation wards in which patients are kept till the character of the disease is known; a large demonstration room; two dining rooms for convalescents and a reception room. The building is strictly fireproof; there will be 57 physicians on call, with a staff of 12 nurses.

Bill for Tuberculosis Sanatorium Vetoed.—Governor Deneen of Illinois recently vetoed the Glackin bill, which provided for an appropriation of $25,000 for the construction of a sanatorium for the consumptive poor.

American Laryngological, Rhinological and Otological Society.—The eleventh annual meeting of this society will be held at Boston, in the Boston Medical library, on June 5, 6, and 7, under the presidency of Dr. Frederic C. Cobb. The secretary is Dr. Wendell C. Phillips, 40 West 47th street, New York.

Scholarships for Mount Sinai Nurses.—What is to be known as the Murry Guggenheim Scholarship Fund has been established by Mr. Murry Guggenheim. The income of the fund will be used for twelve annual scholarships of $100 each for pupils in the training school for nurses. These will be awarded to the nurses in each class who stand highest in rating, six to junior and three each to the senior and graduating pupils.

A Soul-Storm.—Under the title of "The Morphineuse" Dr. W. L. Howard of Baltimore, whose novel "The Perverts" touched many similar phases of psychical aberration, depicts in *The Arena* for May an episode in the career of a female opium habitué. The sketch is as luridly colored as any fantasy inspired by the drug it deals with.

A New Form of Pasteurizing Apparatus.—The Health Department, under the direction of Dr. William H. Park, is conducting a series of experiments to determine the efficacy of a new pasteurizing apparatus imported from France by Nathan Straus for use in his free milk stations. These machines are said to be superior to the old forms in cheapness of operation, rapidity of action and reliability of results. Economy of fuel and speed in operation are obtained by using the stream of hot, outflowing milk to heat the fresh milk entering, while at the same time it is itself being cooled in the process. Should the tests be favorable it is likely that the new pattern will be introduced into the city hospitals.

Proposed Union of Medical Faculties of McGill and Bishop's.—Negotiations are proceeding with the object of merging the medical faculty of the Bishop's College Medical School into that of McGill University. The students of the former would pass over to the latter, with the same standing, and the various prizes, medals, etc., would also be transferred. No members of the faculty, however, are to assume positions on the McGill medical staff.

Beriberi at the St. Louis Exposition.—In his official report Dr. Leonidas H. Laidley, medical director of the Louisiana Purchase Exposition, reveals the fact that during the exposition there was a considerable outbreak of beriberi among the Filipinos. According to the report there were forty-five cases with three deaths.

Surgeons of the Southern Railway.—The following officers were elected at the meeting of the Associations of Surgeons of the Southern Railway, held at Chattanooga: *President,* Dr. Thos. B. Satterwhite of Louisville, Ky.; *First Vice-President,* Dr. J. H. Mitchell of Mr. Vernon, Ill.; *Second Vice-President,* Dr. R. J. Noble of Selmer, N. C.; *Secretary* and *Treasurer,* Dr. J. W. Ray of Woodstock, Ala., was reelected; *Member of the Executive Committee,* Dr. W. C. Day of Danville, Va.

Essex (Mass.) North District Medical Society.—At the annual meeting held in Lawrence, officers were elected as follows: *President,* Dr. Leslie, Amesbury; *Vice-President,* Dr. William J. Sullivan, Lawrence; *Secretary-Treasurer,* Dr. I. J. Clark, Haverhill; *Corresponding Secretary,* Dr. F. D. McAllister, Lawrence; *Auditor,* Dr. Pierce, Haverhill; *Censors,* Dr. Durant, Haverhill; Dr. Day, Newburyport; Dr. J. F. Young, Haverhill; Dr. Sweetsir, Merrimac, and Dr. Fitzhugh, Amesbury; *Counselors,* Dr. Durant, Haverhill; Dr. L. J. Clark, Haverhill; Dr. J. G. McAllister, Lawrence; Dr. George B. Sargent, Lawrence; Dr. Root, Georgetown; Dr. Atwood, Bradford; Dr. Douglas, Amesbury; Dr. E. H. Noyes and Dr. Pillsbury, both of Newburyport; *Committee on Trials,* J. F. Young, Haverhill; *Nominating Committee,* I. J. Clark, Haverhill and *Alternating Committee,* Dr. Pillsbury of Newburyport.

Norfolk (Mass.) South Medical Society.—The following officers were elected at the recent meeting in Boston of this society: *President,* Dr. John F. Welch of Quincy; *Vice-President,* Dr. N. S. Hunting of Quincy; Secretary and Treasurer, Dr. S. W. Ellsworth of Quincy.

Western Illinois District Medical Society.—The officers elected at the Jacksonville meeting were: *President,* Dr. H. A. Chapin of White Hall; *First Vice-President,* Dr. L. J. Harvey of Griggsville; *Second Vice-President,* Dr. D. W. Reid of Jacksonville; *Secretary* and *Treasurer,* Dr. A. L. Adams of Jacksonville; *Board of Censors,* Drs. Fisher of Alton, Nickerson of Quincy, and Pitner of Jacksonville.

Missouri State Medical Association.—At the annual meeting of the Missouri State Medical Association held in Excelsior Springs, May 16 to 18, the following officers were elected for the ensuing year: *President,* D. C. Gore; *Vice-President,* C. D. Avery; *Secretary,* C. M. Nicholson; *Assistant Secretary,* E. J. Goodwin; *Treasurer,* J. Franklin Welch. Dr. C. M. Nicholson was appointed editor of the journal of the Association and Dr. E. J. Good-

win assistant editor. The next meeting will be held at Jefferson City in May, 1906.

Opening of New Hospital.—The opening ceremonies of the Annex to Sherman Hospital, Elgin, Illinois, were held April 14. The addition nearly doubles the capacity of the institution, which will now accommodate 52 patients. The new building was erected at a cost of about $33,000.

Dr. A. M. Fernandez de Ybarra of this city has recently been appointed corresponding member and official representative in the United States of the Medical Association of Porto Rico.

The Decentralization of State Hospital Control.—Gov. Higgins has signed a bill which repeals the Odell law of 1902 which centralized the control of the State hospitals for the insane in the State Commission in Lunacy at Albany and substituted boards of visitation for local boards of managers for each hospital.

A "Coverer" Fined.—A registered physician in this city was recently fined $75 in the Court of Special Sessions for making out a death certificate to the Board of Health that he had attended a 5-year-old girl when in fact he had not seen her before her death. The child died of bronchitis after being attended by an unregistered physician. His defense was that many of his colleagues followed the same custom of signing death certificates for illegal practitioners, the price of the lie being one dollar.

Opposition to a Sanatorium.—Certain of the citizens of Brooklyn borough are up in arms against a project of the Department of Health to establish a sanatorium for consumptives on Henry street. It is proposed to have the clinic in a four-story building in a thickly settled district, and those who object to it claim that the department's plan will endanger the health of the neighborhood and depreciate the value of the property there.

Dr. Jacob Sobel has been appointed adjunct Pediatrist to the Sydenham Hospital.

Fighting Mosquitos in New Jersey.—The Elizabeth, N. J., Board of Health has undertaken to drain the meadows between that town and Newark in order to reduce the numbers of if not to exterminate altogether the mosquitos that breed there. A sufficient sum has been appropriated to do about two-thirds of the necessary work this season. The Central Railroad of New Jersey will be asked to cooperate to the extent of placing culverts under the roadbed wherever the ditching plan will make that necessary.

The New York Eye and Ear Infirmary.—At the meeting of the Board of Directors of the New York Eye and Ear Infirmary held on April 26, the following appointments were made: Drs. Walter B. James and Walter Lester Carr, *Consulting Physicians;* Dr. George T. Elliott, *Consulting Dermatologist.*

Meningitis in Europe.—Several cases of cerebrospinal meningitis have occurred in Irthlingborough, England, four in one house. In Prussia there have been 1,935 cases and 994 deaths since April 30, and in Silesia 1,814 cases and 932 deaths.

Dr. John F. Winn of Richmond, Va., has been appointed Professor of Clinical Obstetrics in the University College of Medicine.

Providing a Site for a State Hospital.—The Board of Estimate of this city has asked the trustees of Bellevue and allied hospitals for a report on the plan for the city to provide a site for a State Hospital for the insane. The State has appropriated the sum of $300,000 to build the hospital if the city will furnish a site on Manhattan Island. The State will pay all expenses of maintenance and the hospital will relieve the insane pavilion of Bellevue of most of its patients.

The Late Dr. Albert A. Davis.—The following minute has been adopted by the Society of the Alumni of St. Luke's Hospital:

Dr. Albert A. Davis died in St. Luke's Hospital on May 6, in his sixty-ninth year. He was born in Vermont and was graduated from the College of Physicians and Surgeons in 1864. After a year's medical service in the Union army he became an interne in St. Luke's Hospital and until his death was connected with that institution in the several capacities of resident physician and surgeon, examining physician, attending and consulting physician.

The Society of the Alumni of St. Luke's Hospital wish to express their sorrow at the loss occasioned by his death and their high appreciation of his qualities as a teacher, clinician, and friend. The Society feel that in his removal from among them they have lost one whose intellectual attainments and noble example made him an ideal for the younger generation of physicians to reverence and follow.

Obituary Notes.—Dr. H. W. Westlake of Los Angeles died on Friday, May 12, after an operation for the relief of an abscess of the lungs, at the age of 48 years. He was born in Canada, graduated from the Victoria University in 1887 and went to Los Angeles in the following year. He was a successful man both in his profession and in many business ventures, and devoted a large share of his income to charity, always with the condition that his name be withheld from the public. The beautiful Westlake Park was named for him.

Dr. Erwin Fischer of Pittsburg died May 21 of abscess of the brain. He had been comatose for the greater part of five weeks. His skull was trephined last week by Dr. Carl Beck of this city, but it was not possible to locate the abscess.

Dr. Ernst J. Lowenthal, a retired physician, died in Hoboken on May 14, in his ninety-second year. He was born near Würzburg, Germany, and finished his medical studies there, obtaining his degree in 1839. He took part in the German and Austrian revolutionary movement in 1848 and came to America in 1850. Dr. Löwenthal was one of the founders of the Republican party and was a candidate for presidential elector on the Fremont ticket in 1855. He lived half a century in Hoboken and retired from the practice of medicine twenty years ago.

Dr. Jacob H. Asch died May 19, aged sixty-five years, at his home, in this city. He came to this country as a young man, having received his degree from the University of Berlin in 1864, and settled down to the practice of his profession in this city after a brief residence in Philadelphia.

Dr. John W. Bayne died at his home in Washington, D. C., on May 17, at the age of 59 years. He was a member of the American Medical Association and the Medical Society of the District of Columbia. Dr. Bayne was born in Prince George County, Md., and graduated from the University of Maryland in 1868.

Dr Alexander A. Farris died at his home in Hickman, Ky., on May 12, at the age of sixty-five years. He was a graduate of the Bellevue Hospital Medical College in 1871.

Dr. James H. Hysell of Pomeroy, Ohio, died May 11 at the age of sixty-seven years. He was a graduate of the Medical Department of the University of Buffalo in 1861.

Dr. William M. Line of Aberdeen, S. D., died suddenly on May 9 at the age of eighty-three years. He was born at Carlisle, Pa., and was a graduate of the Jefferson Medical College in the class of 1851.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

HEALTH OFFICERS AND TENURE OF OFFICE—ORGANISMS IN ENDOCARDITIS—ABDOMINAL SECTION IN CONSTIPATION—ELECTRICTY IN ESOPHAGEAL STRICTURE—KAPOSI'S DISEASE—ASSOCIATION OF SCOTCH DIPLOMATS.

LONDON, May 5 1905.

QUESTIONS connected with the temporary appointments of medical officers of health are again to the front. For many years their association has been striving for permanency of appointments but without success, although members of Parliament of both parties who have been interested in the matter support the proposal—an instance of the evil which party government inflicts by setting the good of party before the good of the country. The committee on physical deterioration presided over by the Duke of Devonshire recommended that a medical officer who devotes his whole time to the duties of his office should in no case, unless convicted of misconduct, be dismissed without the consent of the local government board. But politicians are too busy to trouble about the recommendation, and the public health must suffer. Dr. Bond, of Gloucester, whose good work must be known to you, and who has been regularly re-elected for the last thirty-two years, has been dismissed by the sapient electors, because he objected to undertake the care of three additional parishes without extra remuneration. The local Government Board supported his claim, but the Rural District Council went its own way, and Dr. Bond has no redress. Dr. Norman, of the Howard Rural District, has served for twenty-six years, and the council advertised the post as vacant; but as the other practitioners would not supplant him they were obliged to appoint Dr. Norman. It is frequently impossible for a medical officer to do his duty without losing his position. The local authorities who appoint him are interested in obstructing him. To call attention to infectious disease in health-resorts at once incurs the displeasure of his electors; to condemn jerry buildings or unsanitary slums sets up the back of builder and landlord, who probably sit on the councils, and persuade the still more ignorant councillors not to listen to the doctor's fads, which will only add to the rates.

Dr. T. G. Horder has succeeded in cultivating the gonococcus from the blood of a man of 26, admitted to St Bartholomew's Hospital, with malignant endocaritis three and a half months after an attack of gonorrhea. Cultures were made twice and yielded copious growths. A month later the patient died and cultures were made from vegetations found on the mitral valve. Dr. Horder showed slides of the cultures, films and sections through the endocardium to the Pathological Society on the 18th ult.

At the same meeting Dr. Horder related two cases of endocarditis in which the bacillus of influenza had been cultivated from the blood. The first was in a man of 31. Four cultures all yielded growths—some as many as 100 colonies per cubic centimeter. Postmortem a single mass of vegetation was found upon the wall of the left auricle which gave a good growth of b. influenzæ on cultivation and sections though the endocardium showed masses of the same organism. The second case was that of a boy of 13. Blood cultures undertaken twice showed the same. Here again the autopsy gave the same results, a single large vegetation projecting into the mitral orifice gave the organism. In the first case the diagnosis was determined six weeks before death, in the second case five weeks. In both cases marked leucocytosis has occurred. No other organism was found either in the cultures or in the hearts after death. Lantern slides were exhibited. Dr. Bulloch congratulated Dr. Horder on the manner he had worked up his cases, and remarked that of late years it had been more difficult to recognize the influenza bacillus than prior to the epidemic of 1892-93.

A boy of 12 was shown at the Clinical Society (by Dr. M. Fletcher and Mr. Betham Robinson), on whom abdominal section had been performed for chronic constipation and dilated intestine. He had always had a large belly, and last November there was a great increase of the distension with pain in defecation, but without vomiting, and no blood was passed. At the operation the dilatation was seen to extend from the hepatic flexure to the rectum, the upper part of the latter measuring 9¼ inches in circumference. The bowels was emptied *per anum* by manipulation, many pounds of soft, dark feces being forced out. Recovery was satisfactory. In reply to questions Mr. Robinson said no other morbid condition was present, and if recurrence took place he proposed to open the cecum and flush the colon.

Mr. Drew suggested as a cause derangement of the nervous mechanism leading to spasm of the sphincter. Mr. Mankins remarked on the unusual feature of the case in that the colon was affected only below the splenic flexure.

At the same meeting Dr. Savill showed a case of stricture of the esophagus brought on by swallowing in mistake oil of vitriol which he had relieved by electricity. Dysphagia and stricture increased for two years, when a bougie was passed with difficulty. Later the woman learned to pass one and did so before each meal, and so was enabled to swallow minces. But the difficulty returned and in June, 1903, no bougie had been passed for nine weeks and no solids taken. Fluids could be swallowed only when very hot and the patient recumbent. Electricity was tried and great improvement followed, so that in six weeks she could swallow minced meats and gained seven pounds. This continued for eighteen months when a relapse occurred. Electricity was again successful and now she swallows solids without passing a bougie. The electric treatment employed was a constant current of ten milliamperes increased to fifteen for ten minutes, followed by the faradic current and subsequently the combined current for six minutes. The positive pole was applied over the nape of the neck and the negative was connected with an intragastric electrode which was passed down to the stricture, twelve inches from the teeth.

Dr. Fawcett showed a case of Kaposi's disease in a girl of 16. She was noticed to have freckles at 2½; from 3½ to 10 corneal ulcers. For the last two years small sores appeared at intervals, leaving scars. Last January a granulomatous patch appeared to the left of the nose, which increased until March, when she was admitted to Guy's Hospital, the patch then measuring two inches by one and involving the left ala and upper lip. *X*-ray treatment was tried and the mass diminished by one third. The surface became cleaner and did not bleed so freely. There were numerous freckles on the face, chin, neck, shoulders and below clavicles, some also on the fingers, forearms, arms and shins. There were small white, atrophic patches on the cheeks, also thin white scars and talangiectases, small white, flat warts were also present on the arms.

Among other exhibits I may mention tumor of the tongue in a girl of 12, perhaps a condition of lymphangioma, traumatic cephalhydrocele in a boy of 8½ which followed a fall of twelve feet when he was six months old; congenital absence of lateral abdominal muscles with enlargement of bladder and ureters.

The Association of Medical Diplomats of Scotland does not intend to confine its energies to storming the hospital reserves of the English colleges. It has accordingly held a discussion on rheumatism—a large enough subject and still unexhausted. It was opened by Dr. Alex. Morison, who suggested many points for discussion. It was pleasant to notice that at the outset he did justice to the work of the late Dr. Maclagan, for with the progress of bacteriological investigation his real practical advance sometimes is overlooked. His theory had little influence, and is exploded, but his demonstration of the value of the salicyls was a revolution in clinical medicine. Other points mentioned by Dr. Morison are the connection of rheumatism with tonsillitis, endocarditis, chorea, and so on.

Dr. David Walsh contributed a paper on the connection of rheumatism with skin affections. He has held for some years that rheumatism is an autogenetic poison which affects the excretory function of the skin, and if it proves due to a microbe he would expect to find the organism in any cutaneous rash in rheumatic subjects and therefore he is looking for it. He mentioned some conditions of the skin which seem to him connected with rheumatism and cases relieved by salicyls.

Dr. Hawthorne read a paper on some of the practical issues which arise out of the uncertain meaning of the word rheumatism. The public employ the term in a sense very different to that attached to it by most medical men, and the inquiry into the history of children's illnesses will be useless unless this is remembered. The prevalence of cardiac disease in early life might perhaps be restrained by impressing on parents in rheumatic families the importance of sore throats and growing pains. The uncertainty of definition was further illustrated by the names applied to chronic disorders of joints—names which sometimes lead to erroneous and injurious treatment.

The discussion, though interesting enough, suggests that the society, if it continues to work in this line, might do better to restrict its debates to more defined subjects. We are continually met with the word rheumatism in a vague sort of way and contributions to accurate definitions of all affections so termed would be of great value.

On Saturday the sad news reached Liverpool that Dr. J. E. Dutton died in Congoland on Feb. 27th, about the time the expedition was preparing to return. You will remember the important part he took in the previous expeditions, and from what has transpired it is pretty certain that in this he had achieved further distinction. His discovery of a trypanosome in the blood of a European during the first expedition, which he described and classi-

fied as he afterwards did others, led to the discovery of it in sleeping sickness. At the time of his death he was engaged in the investigation of tick fever. He was only 29 but had taken a very high place among scientific investigators, and his name will be remembered among the martyrs of medical science.

I regret to announce the death of Mr. G. R. C. Tichborne, L.R.C.S.I., F.C.I., etc., who has been for many years the chemical adviser of the Dublin Apothecaries Hall. That body, of which eventually he was Governor, was represented by him on the General Medical Council for the last nine or ten years when his profound knowledge of pharmaceutical chemistry was of the greatest service on the Pharmacopeia Committee. He will be greatly missed on the Council, and in Dublin his loss will seem almost irreparable.

OUR VIENNA LETTER.

(From Our Special Correspondent.)

NASAL CONDITIONS AND UTERINE CONTRACTIONS—THE NEUTROPHILIC BLOOD PICTURE—TRAUMATIC CYST OF THE PANCREAS—OPERATIVE TREATMENT OF GASTRIC ULCER.

VIENNA, May 5, 1905.

DRS. JERUSALEM AND A. FALKNER have reported on experimental studies of the relation between uterine contractions and the nasal mucous membrane. The observations which were undertaken as a sequel to the investigations of Fliess, on the same subject, were made on eighty cases in Chrobak's clinic. It was found that women suffering from painful menstruation or severe lumbar pain during the period of cervical dilatation presented characteristic nasal manifestations, consisting in marked swelling and tenderness of the lower turbinate as well as of the tubercle of the septum. By the local application of adrenalin and cocaine the uterine pain was relieved or diminished. In case the pain returned the treatment was repeated at the end of several hours. During the painless interval the contractions continued without interruption. Uterine pain, depending on mechanical factors, such as cervical stenosis, or of inflammatory nature as in gonorrhea, or due to disproportion between the fetal head and the pelvis, were not affected by the cocaine, though after-pains could be relieved by a single application. No results followed the treatment in the case of women without menstrual pain, and although some swelling of the turbinated bone and tubercle was noted, these regions were only slightly sensitive. These observations are quite in accord with the results obtained by Fliess. By irritating the lower turbinated with a probe uterine contractions could be elicited at will in women with dysmenorrhea and the already mentioned nasal condition. In two cases of protracted labor strong pains were produced on stimulating the turbinateds with a very weak faradic current, but in protracted abortion the same measure gave rise only to pain in the abdomen and back, but no visible contractions, and in non-pregnant women there was no result. The experimenters believe that although there is as yet no practical value to these results, they will assist in elucidating the complex connections existing between nose and genitals.

In the Royal Association of Physicians of Budapest, Flesch and Shossberger reported on the fluctuations of the neutrophilic blood picture in infectious diseases. Under physiological conditions mononuclear neutrophilic leucocytes occur in the proportion of 5 per cent.. binuclears 35 per cent., trinuclears 41 per cent., quadrinuclears 17 per cent., and cells with five or more nuclei 2 per cent. In infectious diseases this relationship changes, the polynuclears diminishing and the mononuclears increasing. Flesh and Shossberger considered the following points in their investigations: First, the degree of variation in the neutrophilic picture observed in different diseases; second, what diagnostic or prognostic importance might be attached to such observations; and, third, how these results could be reconciled with the mode of origin of leucocytosis and our general knowledge of hematology. The authors found that under physiological conditions 30 per cent. of mononuclears, 45 per cent. of binuclears, 15 per cent. of trinuclears and occasional cells with five nuclei were seen, and that in the course of infectious diseases the mononuclears increase and the others diminish. The severity of the infection and the termination of the disease are without effect on this change. An increased number of mononuclears are found in varicella, measles, typhoid and usually in rötheln and suppurative processes. In scarlatina, tuberculosis, and pneumonia they are less numerous. The blood picture does not change in diphtheria. These phenomena in most cases confirm the diagnosis, but do not equal a blood count in value. During the incubation period of measles there is a well-marked change in the blood picture. No prognostic indications are yielded by the blood findings. The neutrophilic blood picture is only a symptom of the reaction of the organism, and not a definite manifestation of the condition present.

Dr. Alfred Exner presented in the Association of Physicians a man of thirty-six with a traumatic pancreatic cyst. On the 3d of September he had received in the abdomen a kick from a horse, which caused him to fall over senseless. On the 15th of October he was admitted to the hospital, saying that he had noticed several rays previously the appearance of a swelling in the neighborhood of the stomach. On examination, a cyst-like mass, the size of a child's head, was made out, with its upper portion covered by the stomach, while the transverse colon ran underneath. Sugar was present in the urine, but several days later the tumor became softer, and finally could hardly be detected, and the sugar also disappeared from the urine. During the following days the consistency of the mass changed in this way almost from hour to hour, and as there was no further glycosuria and the patient's condition was fairly satisfactory in other ways, he was discharged from treatment. In January he returned, complaining of pain when at work. The tumor was as large as before, but there was no sugar in the urine. The diagnosis of pancreatic cyst was made and the abdomen was opened in the median line. The mass was found pushing forward the gastrocolic omentum, and this was divided so that the tumor wall could be sutured to the parietal peritoneum. Five days later the cyst was opened with the thermo cautery, and over a liter of clear light yellow fluid evacuated. The discharge of fluid continued for several weeks. The case is of interest, since it afforded an opportunity for watching the gradual development of a pancreatic cyst.

Dr. Bakes delivered before the same society an address on the operative treatment of indurated gastric ulcer. Until recently only palliative measures have been employed in the treatment of this chronic condition, but a permanent cure is not secured in this way, as the ulcer only enters into a stage of latency. The conservative therapy of the disease has already become obsolete, and the possible complications of hemorrhage, perforation, stenosis of the pylorus, and malignant degeneration demand radical procedures. The palliative measures of gastroenterostomy and pyloroplasty do not remove the dangers which existed before the operation, perforative peritonitis and carcinoma being especially frequent. Bakes examined four out of seven cases operated as benign ulcers and found evidence of malignancy in three. While we do not understand the etiology of carcinoma, we do know that the only remedy against it is the knife, and he has accordingly given up the palliative method of treatment and has obtained very satisfactory results by gastrectomy. The dangers of the operation have been greatly reduced in consequence of the modern technical progress, as well as through the means of increasing the patient's powers of resistance. On the day of operation a nutritive enema of brandy and strong coffee is given, the stomach is washed out with weak resorcin solution and the patient is wrapped in blankets. After the operation an infusion of salt solution and tea with milk, by the mouth, are advisable. The method of combined anesthesia is a very important feature. Schleich's infiltration anesthesia is used while the abdomen is being opened, and primary ether anesthesia during the orientation and eventration, after which the operation proper is carried out without any further narcosis until the last steps are reached. This plan has been followed in a very large number of cases, and has been found most satisfactory. The postoperative stage is almost ideal, the patients are able to converse about the operation, and rarely suffer from nausea. The operation can be performed slowly and carefully, every brusque traction of the organs being avoided. As a proof of these statements, Bakes demonstrated a specimen of almost total resection of the stomach with resection of the entire omentum and transverse colon. The operation lasted three hours, and in addition to a few Schleich injections, only sixty grams of ether were used.

In the discussion that followed, Dr. Hans Lorenz observed that resection was the ideal operation, but that, unfortunately, it could not be employed in many, and particularly in the most severe cases, as it is too hazardous for the patient. He reported two cases of Prof. Hochenegg's that had been cured by a simple procedure. In these much emaciated women there were found true penetrating ulcers which had involved the liver and which were torn open. The treatment consisted in tamponade of the space between the liver and the torn ulcer and in making a posterior gastroenterostomy. Permanent cure resulted, whereas a resection would have been very dangerous for these patients.

Dr. Clairmont reported that Prof. v. Eiselsberg also had obtained good results with gastroenterostomy, and called attention to the fact that some ulcers cannot be resected. One patient who had been unsuccessfully treated by internal measures for symptoms of ulcer and hematemesis was operated, and changes in the stomach wall found which pointed toward the cardia as the site of the ulcer. Gastroenterostomy was done, but death followed twenty-four hours later, owing to internal hemorrhage. At the autopsy

a perforated ulcer reaching into the cardia was found, a condition that obviously could not have been treated by resection.

Progress of Medical Science.

Infections of the Respiratory Tract with Influenza Bacilli and Other Organisms, Their Clinical and Pathological Similarity, and Confusion with Tuberculosis.—F. T. Lord presents the following conclusions: (1) Of 186 nontubercular infections of the respiratory tract, observed clinically, for the most part, bronchitis: (*a*) A mixed infection with various organisms has been found in 120 (64 per cent.). (*b*) A comparatively pure infection with one group of organisms was found in 66 cases (36 per cent.). Of these pure infections those due to influenza bacilli comprise the largest group, with a smaller number of cases of pure infection with the pneumococcus, micrococcus catarrhalis, etc. (2) The pure infections, however, tend to become mixed, as the case progresses, and the observer must then remain in doubt, in the presence in the sputum of two or more groups of organisms, as to the relative importance of any one of the infecting agents. (3) In the clinical picture, the symptoms of onset, the course and duration of the different pure infections, there seems to be nothing distinctive. They all tend to set up diffuse or local bronchitis, and a varying degree of bronchopneumonia. The amount of prostration may be as great in one as in the other. (4) The pathological picture in cases of bronchopneumonia, due to the different organisms, likewise seems to be similar in the character of the exudate, its varying extent and intensity and the tendency, in a small proportions of cases, to end in permanent damage to the pulmonary substance. (5) These results of pulmonary invasion are not infrequently mistaken clinically for pulmonary tuberculosis. Of 85 cases of pneumonia, associated with various organisms, well marked localized pulmonary abscesses or induration or both, were found in 8. No tuberculosis could be demonstrated at autopsy. (6) From the clinical resemblance of such cases to pulmonary tuberculosis, the presence of the tubercle bacillus in the sputum must be regarded as the only infallible indication of this condition.

The Paramount Value of Localized Rales as a Sign of Incipient Phthisis.—H. B. Whitney considers all local signs other than râles as relatively unimportant in the diagnosis of incipient phthisis, because they are inconstant and are often of uncertain interpretation. Unquestionably most cases of chronic pulmonary tuberculosis begin at one apex as a mild bronchopneumonia. Percussion alone at the apex is a difficult means by which to arrive at a definite diagnosis, but when ever a few râles are found at the apex of one on both lungs, the diagnosis of pulmonary tuberculosis is almost certain. The author's experience leads him to regard this sign as nearly pathognomonic. Moist râles are most significant. The much rarer sibilant and sonorous râles are less so. In his experience the earliest râles have been found somewhat oftener in the suprascapula fossa that anteriorly. The regions just below the middle and outer thirds of the clavicle are especially fertile fields, while the apices of the lower lobes corresponding to the fourth or fifth dorsal vertebræ also deserve particular mention. It is best to listen first during ordinary respiration; then during a respiratory cycle made up of a rapid and forcible inspiration with open mouth. Next the patient should give a short, quick cough to be followed by an inspiration of the character above described. In general the râles are almost constantly present at a time when other local signs are absent or indefinite. Their practically unmistakable character differs widely from other signs which represent merely deviations from the normal.

New York Medical Journal, May 20, 1905.

Metacarpal Fissure; a Fracture Not Heretofore Described, and Some Points Regarding Treatment of Metacarpal Fracture.—The paper of Carl Beck is illustrated by four excellent skiagrams. He finds that the displacement following metacarpal fracture is decidedly lateral or both dorsal and lateral. Correction of the lateral displacement can be accomplished very simply by lightly pressing rubber drainage tubes between the adjoining interosseous spaces, where they are kept *in situ* by adhesive plaster strips. Thus recurrence of the displacement is absolutely prevented. The hand may then be surrounded by a plaster of Paris dressing or preferably by a moss splint, which, after being dipped in cold water, well adapts itself to the contours of the body. Special attention is called to the occurrence of fissure above the metacarpal epiphysis. In the majority of cases the line of metacarpal fracture is found in the middle of the bone, where it is thinnest. The direction is generally transverse, but the oblique type is sometimes found. When there is dorsal or palmar displacement the fracture signs are well marked, local pain and tenderness, deformity, abnormal mobility, disturbance of function, and sometimes crepitus being distinctly noticeable. There is often local ecchymosis. Should there be any yielding to the finger as it is thrust against the corresponding metacarpal epiphysis the diagnosis of fracture is established. If so, the pain following the manipulation is considerable. As a rule, therefore, these procedures should not be resorted to for diagnostic purposes, because skiagraphy is much safer and entirely painless.

Alkaline Beverages in the Treatment of Pneumonia.—J. B. Todd says that of a solution of two and one-half grains of sodium chloride and one grain of potassium bicarbonate to the ounce of cold water, from six to eight ounces should be given every two hours. The addition of a little lemon juice will make an agreeable effervescing drink. In addition, the patient should be allowed all the pure water desired. In pneumonia we should do all in our power to promote leucocytosis through the entire course of the disease, also to preserve the proper alkalinity of the blood, for upon this depend the functional life and activity of its living cells to perform their work of growth, repair, and also of the removal of waste products, and destruction of the bacteria and their toxines. We should also maintain the normal specific gravity of the blood. When the tissue and blood plasma are reduced in amount, that remaining is increased in density by being overloaded with waste products; the movements of the ameboid cells are hampered, even the integrity of the red cell is impaired. The hemoglobulin change to oxyhemoglobulin is retarded. The alkalinity of the blood can be tested by placing a drop on glazed litmus paper and brushing it off in a minute or so. When the treatment above outlined is maintained the urine amounts to from forty to eighty ounces in twenty-four hours, is light colored, and has an abundance of chlorides. If the urine becomes scanty and high colored, the alkaline saline draught should be increased in amount or frequency. Scanty, colored urine indicates tissue drought, and increased specific gravity of blood; light colored, profuse urine the reverse.

Medical News, May 20, 1905.

Pneumococcus Infection of the Hip.—L. W. Ely reports the case of a boy of four years, whose hip had been swollen and painful for five days. He had been taken with pneumonia two weeks previously, but the parents asserted that the hip gave no symptoms when the child recovered from his pneumonia. Examination showed swelling and infiltration about the joint and the boy was at once put to bed. Two days after the joint was aspirated and found to contain a thick purulent fluid. Under ether an incision was made down to the joint over the head of the femur, and the pus was evacuated. The capsule was found torn and the head of the bone eroded. A counter opening was made on the inner side of the thigh, and drainage tubes were inserted. A specimen of the pus "contained organisms identified as pneumococcus." The identification was morphological only. Some days later an incision about two inches long was made down to the periosteum, over ninth rib. The periosteum was divided and pushed away, and about one inch of the rib was resected. Pleural cavity opened. A quantity of yellow pus exuded, composed chiefly of fibrin. No bacteria found. Tube inserted. Dry dressing. The patient did well for a while, but a later rise of temperature necessitated another opening into the joint. Death resulted four days later, there having been considerable bleeding from the anterior sinus of the joint wound. No autopsy was held.

Pneumonia; Etiology and Epidemiology.—E. F. Wells reviews the history of the epidemiology of this disease. He finds that the pneumococcus is present in the fauces and neighboring cavities of very many healthy persons. It was found on the tonsils of 45 out of 135 persons. In this location it appears to be harmless, producing pneumonia only when it reaches and develops in the pulmonary alveoli. Any condition which renders the laryngeal and bronchial reflexes paretic, as, *e.g.*, prolonged exposure to cold, privation, exhaustion, or even profound sleep, may permit the gravitation of pneumococcus-laden secretions from the upper respiratory passages to the alveoli, and this is probably the usual route followed by the infectious germ. It is probably disseminated in the main by coughing and sneezing, the pneumococcus-laden secretions being thrown into the air as a spray, and thus inhaled by others. This assumption, considered as being true, explains many of the well-known etiological facts of pneumonia. Thus it would reasonably explain the notorious increase in the prevalence of the disease; its increasing severity and danger; the acknowledged dangers attending the congregation of people in public places, especially at times when many persons are coughing and sneezing; the occurrence of recurrent and family cases, house and local epidemics, etc.

American Medicine, May 20, 1905.

Mitral Stenosis.—Frederick P. Henry says the diagnosis of mitral stenosis in the first stage is comparatively easy. At that time there is a presystolic murmur easily recognized as such by the fact that it is followed by the first and second sounds, both audible at the apex. The second stage is indicated by disappearance of the second sound at the apex, this being due to dilation and hypertrophy of the right ventricle and feeble propulsion of blood into the aorta. The presystolic murmur continues. According to the literature the onset of the third stage is, in contradistinction to this, marked by disappearance of the presystolic murmur and the establishment of signs of tricuspid regurgitation. Dr. Henry has found it is only exceptionally that the presystolic murmur disappears with the onset of signs of tricuspid regurgitation. Again and again he has heard a typic low-pitched, rumbling, presystolic murmur, coinciding with pulsation in the veins of the neck, a few hours before the death of the patient. Another phase of mitral stenosis which Dr. Henry emphasizes is an extreme arrhythmia, a veritable delirium cordis, which may persist without intermission for months or even for years. In such cases there is no murmur, and in them it is impossible to distinguish the sounds from each other. The arrhythmia may continue indefinitely and constitute the chief expression of the lesion. The clinical syndrome of these cases is the following: Marked anemia, with somewhat dusky skin and cyanotic lips, a tendency to bronchial catarrh, marked periods of improvement, with little or no diminution of the arrhythmia, and no edema whatever, or none until shortly before death.

Graves' Disease and Parathyroid Therapy.—James J. Walsh reports four cases of Graves' disease treated with desiccated parathymoids on the principle suggested by Gley of Paris, Munk of Berlin, and confirmed by MacCallum of Baltimore, that it is the absence of the parathyroid glands in the neck which produce the symptoms of Graves' disease. In two mild cases, the remedy seemed to produce a good effect. Walsh concedes suggestion plays a large rôle in the relief of the symptoms in milder cases of Graves' disease. In two severer cases, the remedy failed utterly to give relief and in one case seemed to cause an exacerbation of the symptoms somewhat as if thyroid extract were being given. It is not absolutely certain that the parathyroid material was absolutely free from all admixture with thyroid substance, though it was very carefully prepared for these cases.

Infection of the Urinary Tract by the Colon Bacillus, Simulating Uremia.—James Rae Arneill reports a case of a woman of 60. There was marked constipation, absorption of toxins, autointoxication, irritation of the kidneys by the intestinal toxins, diminution in secretion, and infection of the urinary tract by colon bacilli, which probably migrated through the tissues from the distended colon. The symptoms were partly due to the kidney condition and partly due to the absorption of the intracellular toxins of the colon bacilli. Repeated chemical analyses followed by microscopic examinations of the urine were made before the diagnosis was finally established.

A New Asiatic Blood Fluke.—Ch. Wardell Stiles calls attention to the fact that the newly described Chinese blood fluke (*Schistosoma cattoi*, 1905) may be identical with a fluke (*S. japonicum*, 1904) described for man and cats in Japan. The new species is characterized by the absence of spinose warts on the male and the absence of spine on the egg, while the African blood fluke (*S. hæmatobium*) has spinose warts on the male and a terminal or subterminal spine on the egg. Clinically, in cases of infections with the African fluke both vesical and rectal symptoms have been reported, but all reported infections with the new Asiatic fluke have thus far been intestinal. Another important clinical point is the possibility that some of the cases of cerebral distomatosis, heretofore attributed only to the lung fluke (*Paragonimus westermanii*) may possibly be due to the new Asiatic blood fluke.

Journal of the American Medical Association, May 20, 1905.

The Treatment of Bone Cavities.—The difficulties of properly producing obliteration of bone cavities in surgery are noticed by J. E. Moore. The dangers of infection, the slowness of healing, etc. He has had the best results with von Mosetig's mixture of sixty parts iodoform, forty parts spermaceti, and forty parts of oleum sesami. This, uniformly mixed at a temperature of 50° C., can be poured into the cavity, where it immediately solidifies. It does not act as a foreign body or a culture medium, nor does it cause iodoform intoxication, but it is gradually absorbed and replaced by new tissue. The cavity, of course, should be dry and sterile. The periosteum is closed with catgut after the mixture has been put in and the integument with fine silk. While it cannot be used in acute osteomyelitis, in other conditions he finds it better than any other method. Four cases are reported.

Cesarean Section for Placenta Prævia.—R. W. Holmes holds that cesarean section for placenta prævia lowers the fetal mortality 30 per cent., but increases the maternal death rate nearly threefold. Approximately, the mother is sacrificed for the uncertain chance of life of the child. He questions the statistics somewhat, holding that some maternal mortality is unrepresented. A rigid os is one of the rarest complications of placenta prævia; most cases so diagnosed are, he holds, wrongly so considered. A true cicatricial cervix or rigid cervices of old primiparæ may afford an indication for cesarean section in placenta prævia. Pelvic contractions are indications for cesarean section in the presence of prævial hemorrhage, the deformity, not the prævia, being the determining indication. The earlier the interruption of gestation, other things being equal, the more may the pelvic deformity be disregarded. Usually the condition is not recognized until hemorrhages appear. Cesarean section for placenta prævia will never have so low a maternal mortality as when done for a pelvic indication. Repeated examinations for diagnostic purposes must be made, and the temporary use of a vaginal tampon may be required until the patient can be transported to a hospital or due preparations be made for operation. The acute anemia and the anatomic conditions postpartum add special danger to the operation. Suitable cases for cesarean section usually call for operation independent of the fetal condition, as the primary object is to save the life of the mother. It should be a last resort, and if an abdominal operation is forced on the obstetrician he should remove the uterus as a prophylactic against hemorrhage and infection.

Empyema Treated by Perthes' Method.—W. S. Cheesman reports a case of empyema with extensive lung compression, in which it was at first impracticable to resect a rib, and therefore a simple incision was made and a drainage tube inserted. Six days later the tube tore loose and was sucked into the cavity. This necessitated what he wanted to do at first—the resection of about three inches of the eighth rib in the midaxillary line with freer drainage and the recovery of the lost tube. For three weeks all went well, but when it became evident that the lung was not going to expand, and he therefore installed a vacuum apparatus after the method of Perthes, but simpler, using instead of Perthes' complicated appliances a dentist's saliva extractor connected with the water faucet in the room. To secure a good flange on his drainage tube, he used two rubber bicycle valve stems cemented together; this, with an air-tight dressing, worked satisfactorily, the suction being perfectly regulated by the force of the current as the faucet was turned off or on. The lung began to expand at once, and in seven weeks the use of the pump was discontinued, only a small sinus and pocket of pus remaining. This soon closed and the patient made a good recovery. While the Perthes method may not be adapted to very old chronic cases of adhesions, Cheesman has confidence in its value for cases in which the lung does not expand, though still expansible. No hospital care is necessary; all that is needed is running water and a faucet. He insists on the importance of properly securing the drainage tube; neither transfixion with a safety pin nor sewing it to the skin is sufficient, in his opinion.

Resection of the Stomach.—W. A. Clark reports a case of malignant disease of the stomach involving a large part of the greater curvature and posterior wall, leaving the pyloric and cardiac orifices intact. It was operated on by removing the whole middle section of the organ, leaving only a small portion near each orifice and making an end-to-end anastomosis. A number of enlarged glands were also removed. The patient was fed by enema for a week, after this a gradually enlarged diet was given till the forty-second day, when a small rare steak was allowed. He was discharged from the hospital sixty-seven days after the operation. He reported again two and a half months later, suffering only from a small sinus as the result of the operation. The case is reported as of interest, because of the extensive malignant disease without any very prominent symptoms, and as illustrating the advantages of early diagnosis.

The Lancet, May 13, 1905.

Anatomical Peculiarities of a Gall Bladder and an Appendix.—F. Lemon reports two interesting conditions which came to light during operation. In one, which was an abdominal section for gall-stone disease, the anterior surface of the right lobe of the liver presented what seemed to be a hydatid cyst. On lifting the liver forward, a similar projection appeared on its posterior surface, which when viewed through the substance of the liver was quite translucent. It was in the normal position for a gall-bladder, but the surfaces, both anterior and posterior, were continuous with the liver substance. As no gall-bladder could be discovered an incision was made on the posterior

surface into the swelling when bile gushed out, and on further exploration two large gall-stones. The edge of the incision into the gall-bladder at the time of operation was at least three-eighths of an inch thick, the circularly arranged coat of the gall-bladder being marked off very definitely from the liver substance on the one hand and the mucosa, etc., of the bladder on the other. In the other case an appendix operation, elevation of the cecum, showed on the anterior cecal surface a small elevation about five inches from the extremity of the gut, from which a little pus oozed. At first sight it looked like a perforation of the cecum itself, as no trace of the appendix connected with it could be seen, but on further examination a little loop of appendix with a diameter of half an inch sprang from the extremity of the gut and, passing upwards, appeared to end in the cecum half an inch away from its origin. No elevation appeared on the smooth peritoneal surface to indicate that the loop had any connection with the perforated elevation four and a half inches distant. However, taking the loop as a guide and carefully dissecting away the peritoneum the appendix was traced till it ended in the elevation. The appendix was then stripped off the cecum and removed in the ordinary manner. The exposed surface beneath was the muscular tissue of the cecum and it bled freely. Recovery from operation in both cases was without incident.

Cesarean Section for Congenital Malformation of the Cervix Uteri; Recovery.—The patient of H. T. Skae was a primipara aged twenty-four years, whose labor pains began at seven and one-half months of her pregnancy. Examination showed an apparent absence of the cervix. The usual phenomena of a dry labor appeared. On further examination it was found that the vaginal cervix was represented by a small flat, warty projection, somewhat irregular and quite hard and firm. At its center was the os, so small as to scarcely admit a probe. The projection was placed almost in contact with the rectal wall, the posterior fornix being almost unrepresented. A slimy, purulent discharge was oozing from the opening. The fetal head could not be distinctly felt through the vagina. No fetal movements could be felt and the heart sounds were not to be heard. It was evident that there would be much difficulty in introducing any instrument to dilate the os and further, that any attempt to dilate would inevitably result in rupture into the rectum. And as it appeared advisable to sterilize the patient by tying and dividing the Fallopian tubes abdominal cesarean section was decided upon. (Permission to sterilize was, however, subsequently refused.) Abdominal section and opening of the uterus showed a decomposed fetus and a putrid placenta attached to the posterior uterine wall. It was difficult to drain the uterus perfectly and there was a slight febrile reaction for some few days, but the patient made a good recovery.

Symptomatologie et Diagnostic de l'Angine a Spirilles et Bacilles Fusiformes (Angine de Vincent).—H. Vincent, writing in French, gives an outline of this malady and an exhaustive bibliography. Nothing, however, is presented which has not already appeared over and over again in the special journals. He makes, in short, two forms of the disease: one, the diphtheroid, occurring in only two per cent. of the cases, and the other the common ulceromembranous variety. The smear test is the more satisfactory, as no media have yet been found in which the organisms will grow with any certainty. An illustration is inserted in the paper showing both forms of the pathogenic bacteria. This form of angina is quickly cured by local applications of tincture of iodine. The remedy should be applied by friction on a cotton carrier twice daily.

British Medical Journal, May 13, 1905

The Logical Basis of the Sanitary Policy of Mosquito Reduction.—Ronald Ross sums up his arguments on this subject as follows: There must be for every living unit a certain distance which that unit may possibly cover if it continues to move all its life, with such capacity for movement as Nature has given it, always in the same direction. This distance the writer calls the limit of migration, because scarcely one in many billions of living units is ever likely to reach it, not because the units do not possess the capacity for covering the distance, but because the laws of chance ordain that they shall scarcely ever continue to move always in the same direction. Owing to the constant changes of direction which must take place in all random migration, the large majority of units must tend to remain in or near the neighborhood where they were born. Thus, though they may really possess the power to wander much farther away, right up to the ideal limit, yet actually they generally find themselves confined by the impalpable but no less impassable walls of chance within a much more circumscribed area, which may be called the practical limit of migration—that is, a limit beyond which any given percentage of units which we like to select do not generally pass. This reasoning the writer applies to the case of immigration of mosquitos into an area in which their propagation has been arrested by drainage and other suitable means. The subject of mosquito reduction cannot be scientifically examined without mathematical analysis. It is a part of the mathematical theory of migration—a theory which the writer believes has not yet been discussed. He concludes that the mosquito density will always be reduced, not only within the area of operations, but to a distance equal to the ideal limit of migration beyond it. On the boundary of operations the mosquito density should always be reduced to about one-half the normal density. The curve of density will rise rapidly outside the boundary and will fall rapidly inside it. As immigration into an area of operations must always be at the expense of the mosquito population immediately outside it, the average density of the whole area affected by the operations must be the same as if no immigration at all has taken place. As a general rule for practical purposes, if the area of operations be of any considerable size, immigration will not very materially affect the result. The writer believes that antipropagation measures must always reduce the mosquito density in spite of the results which have been reported.

The Cause and Treatment of Pruritus Ani.—F. C. Wallis has found in over 90 per cent. of these cases which he has examined, a shallow ulcer situated between the two sphincters. It has been more often in the posterior segment than in the anterior and generally near the dorsal midline. In some cases there is more than one ulcer, and in others there are various clefts which almost or entirely surround the bowel. The writer believes that the method of fusion of the proctodeum with the blind end of the gut is the cause of this frequent ulcer. The lining of the proctodeum is thin and is scantily supplied with blood vessels. Thus abrasions here are easily brought about. They rarely heal of their own accord. The ulcer exudes an irritating secretion which causes pruritus. The writer gives the ordinary preparation for a rectal operation. It is well for the patient to give up about two weeks for the treatment. When he is anesthetized, the sphincter is moderately stretched, and the ulcer or ulcers are brought into view and treated with the electric thermocautery. The cautery is also applied to the thickened skin as well. Vaseline is applied to the cauterized area, and a morphine suppository inserted into the bowel. A pad of wool is held in place by a T-bandage, and the patient is put back to bed. On the third night a purge is given, and a warm boracic bath is taken twice a day. The skin is then thoroughly dried and powdered with starch and zinc powder, and a small piece of cotton-wool covered with powder is introduced just inside the sphincter. The irritation ceases at once or after a few days. Even out-patients are treated either with lactic acid or with the thermocautery. The results of this treatment are most gratifying.

Congenital Hypertrophy and Dilatation of the Sigmoid Flexure.—W. F. Brook reports a case of this kind. The patient was a woman twenty-one years old. The history shows that the affection was congenital without any doubt. An abdominal tumor which developed recently was diagnosed as a solid ovarian tumor of the left side. Operation showed the tumor to be a fecal concretion. At this time also the condition of the sigmoid was discovered. The bowel incision was closed and infolded by three continuous stout catgut sutures, each including a greater length than the previous, so that ten or eleven inches of the loop were narrowed down by an extent varying from three and one-half inches in the center to one inch at either end. The abdomen was closed without drainage and the patient made an uneventful recovery. A few days ago she declared that with the help of abdominal massage and an occasional aperient, not oftener than once a week, she had been free from constipation and had had a daily action of the bowels since leaving the hospital. She had suffered from constipation ever since her earliest memory. The mother stated that the trouble dated from birth.

Berliner klinische Wochenschrift, May 1, 1905.

Kelling's Serum Reaction in Carcinoma.—Fuld undertook a series of control observations in order to determine the value of Kelling's assertions regarding the precipitin reaction in malignant disease. The latter author believes that carcinoma is the result of implantation in the body of foreign embryonal cells derived usually from articles of food, and he claims by carrying out the precipitin reaction with the blood of patients and solutions of various animal albumins, particularly chicken and pig, to be able to diagnosticate cancer in obscure cases. Fuld repeated Kelling's experiments with more or less closeness, but reached very unsatisfactory results. Only once out of sixteen undoubted cases of carcinoma of the gastrointestinal canal was there any semblance of a positive reaction, and this was not at all typical. Fuld therefore comes to the conclusion that the reaction described by Kelling does not occur with suffi-

cient regularity either to be of use as a diagnostic measure, or to serve as confirmation of Kelling's theory as to the etiology of cancer.

The Treatment of Epidemic Cerebrospinal Meningitis.—Ruhemann warmly urges the use of sodium iodide in this condition and describes an apparently hopeless case in which its administration was followed by remarkably prompt curative effects. The sodium salt, he says, differs from potassium iodide and the newer iodine combinations in the rapidity with which it gives up in the body its iodine in the nascent state through the action of the hydriodic acid formed. This is shown by the promptness with which the taste of iodine becomes perceptible in the mouth after injection of the drug beneath the skin of the forehead or neck. The author has on other occasions called attention to the value of this salt in certain diseases of the cerebrospinal system, and he says that in cerebrospinal meningitis it will do no harm, while he is convinced that it will be of service and will certainly prevent the development of, and relieve already existing, cerebral disturbances. The drug may be administered subcutaneously or by mouth, in the former case the addition of a little eucain obviates the slight pain attending injection. He suggests the use of a one to twenty solution of sodium iodide with .3 g. of eucain to each 20 c.c.; one to two centigrams of this may be injected in the neighborhood of the head, two or three times a day. If lumbar puncture is done, three to four centigrams might be injected.

Münchener medizinische Wochenschrift, May 2, 1905.

The Nature of Progressive Myopia.—Seggel summarizes his views as to the origin and progress of myopia as follows. Myopia is the result of weakness of the posterior portion of the sclera and depends largely on absence or deficiency of elastic fibers in this membrane. Under these conditions the permanent tension due to the pressure of the lateral eye muscles causes lengthening of the saggital ocular axis. In addition to the number of elastic fibers present, the thickness of the sclera also is important regarding the refraction later on, a thin sclera at least predisposing toward myopia, while a thick one tends to prevent it. The stretching of the sclera at the posterior pole is accompanied by a pulling of the inner membranes and therefore of a diminution in visual acuity and light preception. These two functions may also be injured and this even in the emmetropic or hypermetropic eye if the ciliary muscle is weak or poorly developed. Each of these three defects is congenital and therefore hereditary, and all three together, or the first and second alone, lead to progressive myopia. By the selection of proper spectacles and especially under good hygienic conditions, even though the onset of hereditary myopia may not be prevented, its progress and injury to visual acuity and light perception may be checked.

Antithyroidin in Exophthalmic Goitre.—Lomer says that the antithyroidin of Moebius consists of the serum of sheep that have had the thyroid removed six weeks before the first bleeding. One-half per cent. of carbolic acid is added, so that the preparation keeps indefinitely. It is administered by the mouth with the object of neutralizing the toxic substances formed in Graves' disease, and numerous authors have reported good results from its use. Lomer describes its application in a well-marked case in which the appearance of the goitre had been preceded by profound psychic disturbances. The remedy was not used for a very long period, apparently only during about two weeks, 110 c.c. of serum being administered, but marked improvement, particularly in the cardiac conditions, followed. The pulse became slower, stronger and more regular, but the effect was not permanent, so that the author concludes that the preparation is an excellent symptomatic remedy, but that it is not curative.

A Case of Acute Circumscribed Edema with Orthostatic Albuminuria.—Rubens describes this case in which two obscure conditions were combined in the same person. The patient was a girl of fifteen years, who apparently was well in all respects, and had never had any serious illness. At times localized swellings appeared about the face and in the pharynx or on other parts of the body, and after lasting one or two hours disappeared again. On examining the urine it was found to contain albumin, but on putting the patient to bed this promptly vanished. It was then found that the urine first passed in the morning was normal, but that obtained a few hours after rising contained albumin, that is, the case was a typical one of orthostatic albuminuria. The author believes that this case affords evidence in favor of Senator's theory that orthostatic albuminuria is due to angioneurotic changes in the kidneys, and he suggests that some irritation from the gastrointestinal canal probably underlies the occurrence of the phenomenon both on the surface and in the kidney.

Deutsche medizinische Wochenschrift, May 4, 1905.

Protective Inoculation Against Typhoid.—Bassenge and Mayer, by proceeding along the lines suggested by Briegner and Mayer, who extracted active substances from living bacilli by agitating them with distilled water, have succeeded in producing a preparation which, when injected into the human body, provokes the formation of bodies protective against typhoid infection. The preparation, which does not contain any bacterial bodies, is a clear, yellowish, slightly opalescent fluid which can be rendered permanently aseptic by the addition of three-tenths per cent. to five-tenths per cent. of carbolic acid. The local reaction produced on injection is not severe, and in some persons the general reaction is very slight, while in others there is a feeling of fatigue and moderate headache. The preparation keeps well and its dosage may be accurately graduated. A single injection of 2 c.c. suffices to cause the production of very marked quantities of bacteriolytic substances which are still demonstrable in the blood six months later. The experimental data obtained in testing the preparation on a number of healthy people are given at length.

Cerebrospinal Meningitis in Upper Silesia.—Radmann gives some details concerning the epidemic of cerebrospinal meningitis still raging in Silesia and other Prussian provinces. This region is that through which epidemics usually reach Germany from the East, and the author fears that the disease may continue to spread. The epidemic has already attained unusual proportions, which have surpassed all previous records, and although the bad hygienic conditions common throughout this territory undoubtedly favor the propagation of the infection as they did in the former typhoid epidemics, conditions are now better rather than worse, so that the continued advance of the disease indicates its virulent type. The mortality has been unusually high, approaching seventy per cent.; and the malady is also much more contagious than formerly. In numerous instances group infection among several members of the same household were observed by the author and he is led to believe that in some cases the period of incubation may be only one and a half to two days. The disease has been especially marked among children, only four per cent. of the patients out of three hundred cases in the district of Kattowitz being adults. It was noticed that in cases in which a marked eruption appeared the course of the disease was remarkably light and what were certainly abortive attacks of the disease were observed. In regard to treatment nothing hopeful is said, the conventional methods all appearing to be without great effect. Symptomatically, prolonged warm baths and warm packs were of most value.

Functional and Nervous Disturbances of Telephone Operators After Electric Shocks.—Wallbaum says that the injuries received by telephone operators in the course of their work have not received sufficient attention. It sometimes happens that shocks of greater or less severity are received and the author gives the histories of several such cases in which the consequences were rather serious. According to the nature of the accident and the powers of resistance of the sufferer the first symptoms comprise fainting, clonic convulsions, attacks of weeping, swelling of the extremities, especially on the injured side, and disorders of sensation. Later on, severe headaches and dizziness appear, as well as erratic neuralgic disturbances which are most prominent during cold or stormy weather. Cramplike abdominal pain, hemiplegia, vasomotor paresis, and other evidences of nervous exhaustion such as the loss of power of mental concentration, are also observed. One important symptom which was noticed in all cases was cardiac weakness, evidenced by irregularity of the pulse, precordial pain, palpitation, etc., and the author makes this group of manifestations responsible for much of the great weakness and prostration complained of. The prognosis is bad as regards permanent resumption of telephonic work, for although great improvement may be obtained, the shock to the nervous system is too great to permit of complete restoration. The treatment consists mainly in suggestion, static electricity, massage, and baths. Faradic electricity and bromides should be avoided. The author recommends greater care in selecting young women for these positions, and the family history should be carefully inquired into. Applicants in whose families mental disorders or nervous diseases have occurred should be excluded, and those whose parents have died of a severe chronic malady should be tested with especial care as regards the nervous and vascular systems.

French and Italian Journals.

Serious Sequelæ of Taxis in Cases of Hernia.—M. Savariaud reported two cases of this nature. The first patient was a man thirty-nine years old, who had suffered from an inguinal hernia for twelve years. It had grown to the size of a child's head. The hernia became strangulated and the patient passed an entire night in great suffering. He vomited frequently. In the morning, a physician made an effort to reduce the hernia by taxis. It suddenly entered the opening from which it had been

protruding, and the patient experienced great relief. Nevertheless, neither stools nor gas were passed by the anus. Fecal vomiting began. Intestinal paralysis was diagnosed, and warm injections were given. The writer was then called to see the patient, and in spite of the apparently good condition of the latter, he suspected reduction *en masse* of the hernial tumor. Incision showed that the hernial sac had been pushed back into the abdomen, but the neck of the sac was still causing strangulation. It was cut in two places, thus releasing the strangulated gut. The intestine did not show any serious lesion, and was returned into the abdomen, although with some difficulty, on account of the distention of the abdomen. Recovery was uneventful. In the second case, when the vomiting became fecal in nature, operation was performed. The groove caused by the strangulation had become effaced, but the intestine was discolored and the mesentery was ecchymotic. The writer believed it to be a case of paralyzed ileus which had been caused by too vigorous taxis. The patient died. These cases point to the importance of making moderate taxis if this maneuver is undertaken at all. They also show that after taxis, even if the patient appears to be relieved, if vomiting continues, surgical intervention is indicated.—*La Tribune Médicale, May* 6, 1905.

Digestive Disturbances of the Infant Due to Excess of Fat in the Mother's Milk.—Planchon declares that in the milk of some women, too large a proportion of fat is present, especially in those whose diet is too abundant. Children who take this milk, increase in size, although they take less milk than the quantity which is considered necessary. They often show digestive disturbances, such as vomiting, diarrhea, and so on. These troubles in some cases do not appear at first, but develop gradually, becoming serious if measures are not taken to remedy them. In changing the regime of the mother, the composition of the milk can be modified. Treatment for the mother consists in exercise and in forbidding the foods which are too rich in nutritive materials, such as meat, alcohol, wine and beer.—*Le Bulletin Médical, May* 6, 1905.

Poisoning Due to Cream Cakes.—M. P. Carles, in speaking of many recent cases of poisoning due to cream cakes, states that until recently the explanation has been that it was due to the formation in the cream of ptomains resulting from the development of special microbes which found in this substance a favorable medium. The writer suggests several other solutions for this problem. He thinks that it is worth while to enquire into the nature of the eggs that were used in cooking, if they were duck's eggs, and in what conditions the fowls that laid the eggs lived. He then speaks of the disagreeable character of the flesh of mature ducks, and describes their ordinary habits. They swim in muddy water, and eat plentifully of organic débris which is often in a condition of putrefaction. It seems possible that these toxins that they ingest become disseminated throughout their organism, even becoming incorporated in their eggs. If this is true, it is easy to see that people who eat this flesh and these eggs will feel the disagreeable consequences.—*Revue Française de Médecine et de Chirurgie, May* 8, 1905.

Contribution to the Study of the Independence of the Hepatic Territories.—Pincherle, introducing phosphorus into the stomach of rabbits, having previously ligated the pylorus, has obtained very typical partial steatosis of areas in the left lobe of the liver, with intense necrotic lesions, especially in the periportal spaces. Introducing phosphorus into various parts of the intestine, after ligature of the duodenum near the pylorus, he has produced fatty degeneration of a territory in the right lobe, always with marked necrotic changes. In the rabbit, therefore, the introduction of phosphorus into different parts of the gastrointestinal tube determines steatosis of different portions of the liver. Phosphorus, in its absorption, follows the laws of the double portal blood current noted by Ségére and others, that is via gastro-spleno-hepatic left and entero-pancreatico-hepatic right.—*La Riforma Medica, April* 29, 1905.

Two Cases of Foreign Body in the Esophagus.—Vaccari tells us that the soldo, an Italian coin the size of an old copper cent, is generally arrested, when swallowed, above the second tract for stenosis of the esophagus, that is at the level of the sternal fourchette, lying across the esophagus. The higher up it is lodged, the more urgent are the symptoms of foreign body, and so much shorter is the time it takes to reach the position. Treatment should be prompt extraction—by the mouth, if seen quickly, by esophagotomy, if some lesion may be thought to have resulted from the time the coin has been in position. Pneumonia following extraction, is a symptom of lesion of the vagus. In a case observed by the author urgent dyspnea existed a few hours after the coin was swallowed. He attempted to reach it from the mouth, and succeeded apparently in pushing it into the stomach. However, the coin came out with the sound. In another case, of about two years old the soldo had been swallowed nine days before, and it was located by radioscopy in the gullet. Cervical esophagotomy was done, and was followed by a double pneumonia.—*La Riforma Medica, April* 29, 1905.

Albuminuria and Glycosuria from Fatigue.—Guglielmo Gobbi has made observations and urinary examinations of eight men, runners of a race of 26 kilometers, both before and after the race, and gives us the results of his observations. Four of the contestants examined were soldiers and four gymnasts. The author ascertained that before the race they were absolutely sound and healthy, and that examination of the urine showed the kidneys to be in a normal condition. The course was over an ordinary road, with hills and hollows; the day was cold and humid; one-half the course was with and one-half against the wind. The race was run in from one hour and fifty-four minutes, to two hours and forty-five minutes. The first part of the race was run easily, without appearance of fatigue, the second half with evident painful muscular contractions, ending in exhaustion. After the race some showed transient excitations, others absolute exhaustion, but all were recovered in three hours. The urine examined was for less than three hours. There was no relation between the amounts of albumin and sugar eliminated by each individual; there was not relation between the albumin and the amount of sediment for each individual; the amount of urine varied greatly; the amount bore no relation to the abnormal constituents; in two cases a large amount of albumin was present with a low specific gravity, and the amount of total solids was very low in those individuals whe were exhausted and their pulses were very frequent. Seven individuals had albumin in the urine; four had blood; hyaline, granular, and epithelial casts were present in some cases, and sugar in all cases. These observations show more albumin than is normally present from simple fatigue, and indicate a new form of glycosuria. Eight days after the race all had returned to a normal condition. The author believes the albumin to have been due to complex actions of the organism, the results of prolonged fatigue. One element is the irritation by poisons arising from muscular action. There is also a disturbance of circulation, and there might be a reflex influence from nervous disturbance due to excitement. The glycosuria was due to stimulation of the glycosuric center in the bulbar region of the medulla, by the excitement of the race.

Attempts to Find a Specific Remedy for Tuberculosis.—C. H. Cattle, in discussing remedies for tuberculosis, declares that it is questionable whether any purely antitoxic serum will ever succeed, because the toxine of the disease is not widely diffused. In many cases, undoubtedly, the tuberculous process undergoes a spontaneous cure, although we do not know exactly how the victory is obtained. The tissue-cells, especially the leucocytes, probably secrete substances which inhibit the growth of the microbes. Whatever means are used for the arrest of tuberculosis, the object in view can be effected only by assisting the processes by which the natural arrest of the disease is effected. Remedial agents which increase the number of white blood corpuscles have been extensively employed in the treatment of tuberculosis. To this class belong yeast, either crude or in the form of nuclein, and cinnamate of sodium. The tendency of a liberal allowance of food, especially proteid, is to maintain a condition of leucocytosis. Vegetable proteid can be used instead of butcher's meat with equally good results. The objection to an exclusively vegetarian diet is the large amount of waste material. Apart from all questions of treatment, Koch's old tuberculin is a useful diagnostic agent. It is the only preparation known capable of exerting a specific effect on tuberculous tissues. Maragliano's product is one of the best known antituberculous serums. His toxic material is obtained from sterilized cultures which are used for immunizing horses. The result of its use depends much upon the stage and type of the disease. Marmorek has devised another serum, which even in bad cases seems to have the power of reducing the temperature when given in doses of 5 c.cm. daily for four days, followed by an interval of three days' rest. The object in using the new tuberculin is to employ it as a vaccine. Both Koch and Wright have found the agglutinative power of the blood increased by the use of tuberculin injections. Wright has reported remarkable improvement in cases treated by tuberculin as advised by him. The writer concludes that it is yet too early to judge as to the value of either the serum or tuberculin treatment.—*The Practitioner.*

Book Reviews.

Climate and Health in Hot Countries, and the Outlines of Tropical Climatology. By Lieut-Col. G. M. Giles, M.B., F.R.S.C. Indian Medical Service. New York: William Wood & Co., 1905.

This is a popular treatise dealing with personal hygiene in the hotter parts of the world and including a section giving the climatic characteristics of the chief tropical countries. While the book is primarily intended for the guidance of the laity, Lieut.-Col. Giles has included in its three hundred pages many facts unappreciated by the average medical man without tropical experience, and well worth recalling to the attention even of those of long residence in hot climates. The book is not only instructive, but highly readable, as Col. Giles presents his facts entertainingly and frequently forcibly illustrates them by quaint happenings in his own experience. It is scarcely a work to study as a text-book, but rather one to be read at odd times, when in search of entertainment as well as instruction. The book is packed full of common sense, and if its teachings were followed by those going to the tropics, many lives would be saved which are now sacrificed to ignorance. With the recent assumption by this country of vast obligations in the tropics, the subjects treated by Col. Giles become of great personal importance to many of our citizens on duty in the dependencies. Particularly should the work be read by school teachers and other classes of civil servants liable to assignments away from the centers of tropical civilization, where they are largely thrown on their own resources, and the authorities should see to its official supply for such purposes. It is the best book of its kind in the English language, and fills a much felt popular want.

Appendicitis: Its Diagnosis and Treatment. By John B. Deaver, M.D. Third Edition, Revised and Enlarged. Philadelphia: P. Blakiston's Son & Co., 1905.

It is scarcely twenty-five years since our knowledge of appendicitis was placed on a sound, practical basis, yet the subject has grown so both in extent and importance, that a volume of almost 500 pages is found necessary for its proper presentation. Dr. Deaver has had a very large and exceptional experience in the observation and treatment of this disease, and now has the satisfaction of finding a more favorable opinion prevailing as to the propriety of early operation for appendicitis, which he so strongly advocated in the first edition of his book, published nine years ago. The present edition has been enlarged by the addition of several new chapters and illustrations, the former including "The Function of the Cecum and Appendix," "Appendicitis in Children," "Chronic Appendicitis," "Typhoid Appendicitis," and "The Blood-count in Appendicitis." The chapters on etiology, pathology, diagnosis, etc., are all very complete, but greatest interest centers in that on treatment. In this certain radical changes are recommended, particularly in regard to the medical treatment. Deaver continues to urge operation during the first few hours of the attack, in the so-called pre-inflammatory, or stage of appendical colic. Medical measures may be considered as an alternative only in patients in whom operation is impossible or contraindicated. The persistent use of salts he regards as dangerous and harmful, and a cathartic (castor oil or calomel) may be given only at the very onset, if there is a history of the ingestion of indigestible materials. Opium also should never be given until the diagnosis has been established. The general indications for, and the technique of operation, as detailed in the extensive chapter on Treatment, are represented in an excellent manner, and constitute a safe working guide. Taken as a whole, this treatise may be highly commended to both surgeon and internist as a work of reference and instruction. The book is well made and the plates are not only numerous, but well executed.

The Surgical Treatment of Facial Neuralgia. By J. Hutchinson, Jr. New York: William Wood & Co., 1905.

A great deal has been written on this subject, but the only complete review is to be found in Krause's monograph (1896), and this is largely occupied with questions relating to the physiology of the fifth nerve. In the book here reviewed, Hutchinson has brought the matter down to the present time, and provides a good, clear account of a complex and difficult subject. The greater portion of the book is taken up with the discussion of epileptiform neuralgia, also known as tic douloureux. From a thorough study of his own results, and also those of others, Hutchinson concludes that where the neuralgia has already invaded two main divisions of the nerve, the major operation should be carried out as affording the only hope of permanent cure. If the branches are involved individually, resection of any one of them may be tried. Medical treatment, he considers practically useless. He has found that the best results follow the Hartly-Krause operation. Of this, together with most of the others which have been proposed, he gives complete accounts. It has been demonstrated that the risk to life is very small and the prospect of a permanent cure very great with this operation, and he thinks that it is fair to state that the Hartly-Krause method forms one of the most important surgical gains of the last twenty-five years. The book is well written, contains numerous illustrations, and a very complete and satisfactory index and bibliography.

Morphology and Anthropology. A handbook for students. By W. L. H. Duckworth, M.A., Fellow of Jesus College, Cambridge; University Lecturer in Physical Anthropology; Correspondent étranger de la Société d'Anthropologie de Paris. New York: The Macmillan Company, 1905.

The question discussed in the present volume is briefly Man's position in the animal kingdom, and the nature of his ancestors. The line of inquiry embraces the evidence derived from Comparative Anatomy, Human Embryology, the study of Variations (both Anatomical and Morphological), and lastly, Paleontology, or the investigation of fossil animals. First it is shown that man is associated in a natural classification with certain of the mammals; then an inquiry is made into man's ancestral history, that is, of the path of evolution as traced by man. The author himself supplies an admirable summary, which we herewith quote: "The means available for carrying out this inquiry are at present day threefold: (1) embryology, (2) the comparative morphology of the various human races, and (3) paleontology. The importance of the first-mentioned study, viz., embryology, depends upon the well-known generalization . . . to the effect that the individual organism recapitulates in its own developmental history the several stages through which its ancestors passed in their evolution. The second study, viz., the comparative morphology of human races may be expected to reveal the most recent stages only, and to indicate the steps by which the more highly evolved of human beings have arisen through the modification of their lowlier and more archaic brethren. The last-mentioned science supplies information as regards extinct forms of life, some of which may be regarded as at any rate representative of, if not themselves, actually human ancestors."

An Introduction to Dermatology. By Norman Walker, M.D., Fellow of the Royal College of Physicians of Edinburgh; Assistant Physician for Diseases of the Skin to the Royal Infirmary, Edinburgh; Editor of the *Scottish Medical and Surgical Journal*. With 49 Full-page Plates and 50 Illustrations in the text. Third Edition, Revised and Enlarged. New York: William Wood & Company, 1905.

The third edition of this admirable little volume contains a considerable amount of new matter, though as some of the polemical discussions have been omitted the size of the volume is not increased. The newer developments of radio- and electrotherapy are given an amount of space commensurate with the general plan of the work and much of the new material is devoted to these subjects. The plates, both colored and photographic, comprise an excellent series of depictions of the commoner cutaneous disorders and are well adapted to serve for ready reference in doubtful cases. The text is equally practical, and the treatment advocated is thoroughly modern, so that the book may safely be recommended as a concise, well written epitome of dermatology.

Saunders' Question Compends. Essentials of the Practice of Medicine. Prepared especially for students of medicine. By William R. Williams, M.D., formerly Instructor in Medicine and Lecturer in Hygiene, Cornell University; Tutor in Therapeutics, Columbia University (College of Physicians and Surgeons), New York. Philadelphia and London: W. B. Saunders & Company, 1905.

This is a new volume of Saunders' well-known compends. As indicated by the title, it supplies the essentials of the Practice of Medicine. Emphasis has been rightly laid on the more common forms of the various diseases; and throughout the book the requirements of the student have been kept in mind. Points of differential diagnosis have been given the attention they deserve. We are glad to note that the questions have been relegated to the end of the chapter, thus making the text more readable, and at the same time taking away that catechism-like appearance which characterized former volumes of the series. Rightly used this book will be of service to the medical student.

Die Anästhesie in der ärztlichen Praxis. Von Dr. Max Martin. Munich: J. F. Lehmann, 1905.

Dr. Martin's little pamphlet contains a short and clear account of the methods and uses of local anesthesia in medicine and surgery, with special reference to the combination of cocaine and adrenalin. Ethyl chloride is also briefly considered. Precise directions are given, together with the indications and contraindications of the methods dealt with.

Society Reports.

NATIONAL ASSOCIATION FOR THE STUDY AND PREVENTION OF TUBERCULOSIS.

First Annual Meeting Held at Washington, D. C., May 18 and 19, 1905.

(Special Report to the MEDICAL RECORD.)

GENERAL MEETING.

FIRST DAY, THURSDAY, MAY 18.

THE PRESIDENT, DR. EDWARD L. TRUDEAU OF SARANAC LAKE, IN THE CHAIR.

Presidential Address.—Dr. EDWARD L. TRUDEAU of Saranac Lake, in his address, called attention to the many years of unsuccessful labor on the part of the pathologist. He believed that tuberculosis was communicable, preventable, and, in its earliest stages, curable. Ten years ago the reduction of the death rate from tuberculosis was deemed impossible. Organization and cöoperation had been the most important factors in his opinion in bringing about the present excellent results, and were the recognized factors abroad as well as here. An international society was in existence with its headquarters in Berlin, and the speaker was pleased to state that the United States had a representative in that body. He urged that each State should have a representation in the national society in this country, and this society should publish a journal. He then briefly outlined a suggested method of representation. In his opinion, the first important thing was the education of the people and then of the State. Education would mean the early detection of the disease, which would enable the national association to put its heel down on quackery. He believed also that medical students should be better trained in the early detection of the disease, and expressed himself as considering that the value of the tuberculin test had not been fully demonstrated in this connection. He referred to the fact that one of the main objects of this association was the extension and advancement of the study of tuberculosis, and expressed the hope that the United States would no longer be one of the largest borrowers of scientific study. Before many years, he felt that American science would have won its place, but special inducements for the study of the disease, he regretted, were greatly needed. Commenting on research work in the laboratory, he stated that it was one of the most important factors in the study of the disease.

First Vice-Presidential Address.—Dr. WILLIAM OSLER of Baltimore, speaking extemporaneously, dwelt at great length on the value of education in the solving of the tuberculous problem. He called attention to the enormous amount of knowledge already possessed on the subject of tuberculosis, and expressed the fear that perhaps people were sometimes embarrassed by the knowledge they possessed. He stated that the making the knowledge effective, getting sense and getting wisdom was a totally separate and distinct quality from the acquiring of knowledge, and it was most true, as Tennyson said, that "knowledge comes but wisdom lingers." He considered that there were three to educate, the public, the profession and the patient, and the first named he considered very weak. One of the most important duties for the public to perform was the enactment of proper laws, and he heartily recommended the New York laws as good ones to follow on this subject. The proper care of the early tuberculous case, either by public or by private munificence, and the care of the hopeless cases, these being really the ones from which the disease was most often spread, were mentioned as two other important duties of the public. He then called attention to the question of the education of the profession, and particularly in the art of diagnosing cases in their earliest stages, which he felt the profession often failed to recognize. The education of medical students, especially along the line of diagnosis, was urged, and attention was called to the difficulties encountered in giving students the proper amount of practical experience in these cases owing to the scarcity of material, largely due to the fact that hospitals for the study of the disease were made few and far between by the objections of people to have them built in their midst. To at least in part overcome this difficulty, he expressed the hope that every general hospital would have a tuberculosis dispensary in connection with its general dispensary, particularly owing to the enormous educational advantages to the medical students and the great assistance it would be to physicians in referring their cases for early diagnosis. The third part of the education problem, the education of the patient, he considered the most trying and most difficult, particularly as the relatives and friends so often objected to the diagnosis being given to the patient, thus making the physician, in his opinion, *particeps criminis*. He stated that if the national association would stimulate and support work along the line of these educational problems it would do both the public and the profession good. He concluded his remarks with a very glowing tribute to the president, Dr. Trudeau, who, he said, had the true humility of a great man.

Second Vice-Presidential Address.—Dr. HERMANN M. BIGGS of New York discussed at great length the question of the personal registration of all cases of tuberculosis. He referred in detail to the methods employed in New York, showed that infectious disease hospitals had no effect on the public health nor the value of property in their immediate neighborhood, demonstrated that cases of tuberculosis could be kept within thirty or forty feet of scarlet fever and diphtheria patients without any restrictions in their movements and yet without any danger of one to the other, and proved the unreasonableness of the public's objection to such institutions. Taking up the question of enforced registration of tuberculosis, which he claimed did not exist anywhere in this country or abroad except in New York City, with very few exceptions, he heartily endorsed what had been said by Dr. Trudeau and Dr. Osler as to the whole matter being one of education of the public and of the profession. He explained the function of the Advisory Board of the New York Department of Health and urged the appointment of such a board in all large cities, principally on account of the confidence the public seemed to have in the work of the department if approved by this board. As a second important step in this direction, he advised the free examination of sputum to facilitate the early diagnosis and give some return to the physician for his trouble in reporting the case, mentioning the fact that the tremendous increase year by year in the number of free examinations made in New York showed the popularity of the idea. He considered that the public's fear of consumption would largely be removed if people were made to understand how different a disease it was from smallpox, scarlet fever and diphtheria, and especially if they were impressed with the idea that it was only infectious and communicable where simple sanitary requirements had been neglected. He then detailed some of the difficulties experienced in the compulsory reporting of cases, particularly in dealing with the question of duplicates, and stated that without proper registration any systematic scheme would not be operative as it would be impossible to say that apartments occupied by consumptives had been properly disinfected. He called special attention to the fact that the enforced registration caused no publicity, as the Department of Health took no action on any reported case as long as it remained under the care of a physician or removed its residence, in either of which cases the department insisted on being notified. He congratulated the national association on its bright prospect and heartily endorsed all that Dr. Osler had said in reference to Dr. Trudeau.

The remainder of the session was devoted to the passing of resolutions and the making of announcements, among the most important being the tendering of the thanks of the association to Mr. Henry Phipps for his financial assistance in the study of tuberculosis, and the announcement that the dinner the following evening would be in the nature of a testimonial dinner to the president of the association.

SOCIOLOGICAL SECTION.

FIRST DAY, THURSDAY, MAY 18.

MR. HOMER FOLKS OF NEW YORK, CHAIRMAN.

Tuberculosis From the Layman's Point of View.—Mr. HOMER FOLKS of New York made this address. He said that the facts with which the Sociological Section of the Association had to deal were, first, that tuberculosis was the leading cause of death in this country, and second, that in the last two or three decades we had learned some of the most important secrets of the arch enemy. We had discovered the unit of his forces and we knew something of its nature. We knew how to cure a large number of those attacked if only they could be treated in time, and we knew how to capture and destroy the active agent in the spread of infection. The steps that should be taken in the application of our present knowledge to the restriction of the disease had been set forth in several notable papers, especially that of Dr. Biggs, on "Administrative Control of Tuberculosis." Considerable progress had been made in regard to carrying these measures into effect. In New York the results were read in the lowered death rate from pulmonary tuberculosis, from 3.86 per thousand in 1884 to 2.46 per thousand in 1904. The question which inevitably occurred to a layman was that if tuberculosis was a preventable disease why was it not prevented. After weighing all the reasons that were usually given, he had decided that it was because we did not realize the value of public health as an investment; that we were not willing to devote sufficient means to the saving of human life. He said that while we had the greatest possible respect for the efficiency, the expertness and the devotion to the public well-being of our health authorities, we must admit that the sums placed at their disposal were woefully inadequate for the performance of the tasks which were essential in checking this disease. There was only one tuberculosis dispensary in Greater New York. In regard to the educational campaign, he said that thousands of circulars had been printed in many different languages, but he questioned the extent to which they had really penetrated the minds of the people of Greater New York. In a political campaign, each voter was reached through the mail, not once but several times. The postage alone for a single communication was $60,000. When we had the means to carry on a work of such magnitude, we might undertake a campaign and not a skirmish of education. As for the care of consumptives in their homes, the provision of sufficient food of the right sort, adequate medical and nursing oversight, and the provision of sufficient hospitals and sanitoria we are only at the beginning. The practical question was whether knowing how to restrict effectively this terrible scourge, we should be satisfied with a piecemeal method or whether by large expenditures we should accomplish the greatest result in the shortest time. He spoke of the work that could be done by the expenditure of a million dollars a year for the next ten years in the city of New York. He said that when the city was undertaking a great public improvement the benefits of which would be extended over a series of years it did not meet the expense from its current funds, but from the sale of corporate stock, the burden of which was distributed over a series of years. Many of these investments were directly for the health of the people, as in providing parks, playgrounds, baths, hospitals, etc. Why should not an adequate expenditure for the restriction of tuberculosis by all the known methods be exactly of this character, and therefore an appropriate expenditure to be defrayed by the sales of bonds? There was every reason to believe that after the work had been carried on adequately, efficiently and comprehensively for a number of years the need therefor in some respects at least would greatly diminish. The so-called permanent improvements were of service only because they contributed to human well-being, and they were not the only means by which the city contributed to the well-being of its people. Every step taken for the protection of the health of the people, the protection of its food supplies, the care of its sick, the improving of its housing conditions and protection from moral evil was a great public improvement. The benefits derived from large expenditure for the public health could not be converted into cash, but the public health was nevertheless an asset of the highest possible value, contributing to the economic strength of the people, furnishing the foundation upon which the entire superstructure of municipal credit and life was built. No American city could find a more appropriate subject for investment at the present time than in carrying into effect the measures set forth at this meeting for the prevention of tuberculosis. It was not, however, a question exclusively for the city, but was also in a large degree a question for private benevolence. What was needed was not permanent endowments, but unusually large contributions for a comparatively brief period.

Dr. THOMAS DARLINGTON of New York said that he agreed with the chairman on many points. He thought that the stamping out of tuberculosis in this country was simply a question of education of the masses. With plenty of money, we could have the education. It was the duty of the community to take care of those who did not take care of themselves. Health meant the ability to work and to earn wages. Why then should we not spend more on health than on education, for of what use was higher education if we have a dead child. The problem of educating the masses in a great city like New York was an exceedingly difficult one. The death rate from tuberculosis in New York was increasing because of the large number of emigrants who remained in the city; these must be educated. This involved a great expense, because circulars had to be printed in so many different languages. At the tuberculosis clinic attached to the Board of Health there were 3,000 patients treated last year, and 1,100 of them were Russians who had been in this country only two years. In addition to circulars, their homes had to be visited and bad sanitary conditions corrected. Dr. Darlington did not think it would be economy to issue bonds for this work in our large cities. He thought that if we were to gain anything it would depend upon such as a society as this, together with the moral support of this Government and that of other countries.

Dr. ANTONIO STELLA of New York spoke in behalf of the Italian element in New York City. He said that there were about 400,000 Italians in the city, and the majority of this population had a tendency to be sick, and were especially prone to pulmonary affections. Statistics in regard to tuberculosis among the Italians were deceptive, because as soon as the Italian patient was told that he had tuberculosis he returned to Italy and was not registered in the New York Bureau.

Dr. CHARLES F. WELLER of Washington said that the national capital had a very high death rate from tuberculosis, that it was only exceeded by that of Denver and Los Angeles. He said that important legislation had been prevented by one or two Congressmen, and he begged the public to send people who were informed as to the needs of modern preventative social measures, as Washington was very much in need of measures for the prevention of tuberculosis.

Mr. CHRISTOPHER EASTON of Newport, R. I., said that the doctors of that city had been trying to educate the public in regard to the dangers of tuberculosis, and leaflets had been sent to every house there. More money had been spent for leaflets and lectures than for extra food.

Mr. A. M. WILSON of Boston reported that the educational campaign was going on with great strides and that large sums had been given for consumptive hospitals. One of their greatest needs to-day was suitable municipal provision for advanced cases of consumption.

Dr. HERMANN M. BIGGS of New York said that New York had done better in furnishing funds than most municipalities. Recently they had had as much money as they could spend wisely. Education must precede any judicious

expenditure of money. The work could not be carried beyond the plane to which the medical profession had been educated. The education of the people and of the profession demanded an earlier recognition of the disease. There was no use in providing institutions unless the people were educated to come to them. A census taken about three months ago showed 1,800 consumptives under treatment in public and private institutions in the city of New York. From the standpoint of prevention, it was the late case that was the more important and the ones that demanded our care.

Mr. J. H. Lowman of Cleveland, Ohio, said that while money was necessary, it was possible to work while we were waiting for it. He told of the work of a man in Cleveland in removing children from families in which there was tuberculosis and sending them to the country.

Mr. Elwell Stockdale of White Haven, Pa., said that every town should have its tuberculosis association. He thought that it was a work of individual effort and that we did not need to look to the city or the State for aid.

Dr. S. A. Knopf of New York thought that the last speaker was too optimistic. He did not think that a consumptive could be cured for less than $7.00 or $8.00 a week. He thought the question of how to get sufficient money was a very difficult problem.

Mr. Elwell Stockdale said that in the institution to which he referred to cost was $5.00 per week per capita. He did not wish to compare the institution to Dr. Trudeau's sanatorium.

Dr. Henry B. Jacobs of Baltimore said that the cost in Maryland was $8.00 per week, and they were able to send patients for three months at a cost of $96.00. In this way they received more subscriptions and could thus save more lives.

Dr. Irving Fischer of New Haven, Conn., said that if it cost $100 to cure a patient, and without being cured it would cost $300, before the patient died it was more profitable to cure the patient. A man in middle life could earn every working year from $1,500 to $2,000, and an investment of $100 for a return of $2,000 was certainly worth while.

A Working Program for Associations for the Prevention of Tuberculosis—National, State, and Local.—Mr. Edward T. Devine of New York presented this paper. He stated that the ultimate responsibility for the control of epidemics, as for the cure and prevention of disease in general, lay with the medical profession. Responsibility could be devolved upon the medical profession only by meeting the conditions which authoritative medical opinion prescribed as essential. The program which he formulated had ten features: 1. The maximum of fresh air and sunlight for all mankind—at work, at leisure and at sleep. 2. An abundance of simple, and yet sufficiently varied and nourishing food—especially pure milk and fresh eggs. 3. Early diagnosis of every case of pulmonary tuberculosis by the family physician, and the utmost endeavor to secure compliance with his advice as to medical treatment. 4. Registration of all cases, whether in tenements or palaces, city or country—not to be followed by any unnecessary intereference by Health Board inspectors, etc., but enabling the health authorities to know their problem and to deal with it on the basis of complete knowledge. 5. The establishment of hospitals, or whatever other institutions will best serve the purpose for advanced cases, with the two objects in view of making such patients more comfortable and of diminishing the centers of active infection. 6. The establishment on a generous scale of State, municipal and private sanitoria for the treatment of patients in the earlier stages—no expense being spared so far as essentials were concerned and no extravagance being tolerated in non-essentials. 7. Publicity as to the means of preventing infection, and as to other elementary rules of hygiene through every known channel of public instruction: newspapers, schools, the lecture platform, leaflets in all necessary languages, appropriate special periodicals, and instructive visits from physicians, nurses or competent lay visitors. 8. Conference or interchange of views among those who are in any way working at the common task and associations for educational and preventative work. 9. Relief in various forms, but especially in the form of special diet for those who can and must be treated at home and who were not able to provide the necessaries of life, which in some cases included the prescribed diet essential to life and recovery. 10. Further research. More knowledge, better authenticated records, further comparison of results were needed, and for these, more laboratories, endowments and favorable conditions for scientific research, travel for observation and study abroad, and training for fruitful investigation. There was no single procedure for an anti-tuberculosis campaign in any community. The only general principle was to build on local foundations and to incorporate all that was good and applicable in the experience of similar movements elsewhere. Any existing organization, as a medical society, a health board, a civic league, etc., etc. The specific measures for which a local association for the prevention of tuberculosis should work naturally varied with the size and the character of the community in which it was to operate. If there were no special hospitals for consumptives, or separate ward in a general hospital that would be a good objective point of attack. As yet there was no city of considerable size in the United States in which there was even an approach to adequate hospital and dispensary facilities for consumptives. There was also the necessity of educating the rank and file of the medical profession as to the necessity for early diagnosis, registration and protection from infection. After these two great undertakings came the still greater and even more elementary undertaking, namely, the creation of a sound public opinion, midway between indifference and phthisiophobia, and enlightened public opinion in which every one was frightened just enough to act sensibly, and not enough to act foolishly; just enough to insure necessary public appropriations and private donations, but not enough to make it difficult for a cured consumptive to find a job; just enough to cause railroads to disinfect the hangings of a sleeping car but not enough to refuse to an indigent consumptive girl on her way to a sanatorium the charitable reduction which was given to other indigent persons; just enough to cause the city to build a sanatorium but not enough to induce the legislature to permit local prejudice to close county after county to the urgently needed sanatorium.

Dr. Arnold C. Klebs of Chicago said that he would like to see the paper printed in large letters and published everywhere. He thought that more definite work should be assigned to the various associations. State associations should have a definite place, and local associations ought to have their work, and the work should not be duplicated. He heartily endorsed every word of the paper.

Mr. John M. Glenn of Baltimore agreed that Mr. Devine's paper had covered thoroughly and in a suggestive way the general field of tuberculosis associations. Not enough stress had been laid upon the benefits that would accrue to future generations if they were saved from this dread disease. The first thing which the tuberculosis associations should do was to look to the education of the masses and this task required a great deal of patient hammering. Much could be done without money. He considered Mr. Folk's scheme of issuing stock a good one. Pamphlets prepared by medical officers and State Boards of Health could demonstrate the economic side of the question in the loss to the community in wages and in other ways.

Dr. J. M. Wainwright of Scranton, Pa., related his experience in Scranton. Seven men got together and called themselves a Board of Directors for the Study and Care of Consumptives, the object being to maintain sanataria and dispensaries, visiting nurses, etc., and to educate the people regarding this disease. Dr. Knopf of New York delivered a public lecture which created interest and aided in getting money to carry on the work. The legislators

were reached through their family physicians and they finally succeeded in getting such legislation as they desired. He thought it important that local associations should have the cooperation of Boards of Health.

Dr. George M. Kober of Washington thought it ought to be obligatory for all local associations to be in close affiliation with the national associations. He suggested that the question of proper sewage should be considered by the local and state associations, a point that had not been sufficiently emphasized. In 1865 he had noted the relation between increase in the number of cases of tuberculosis and dampness of the soil and improper water supply. Tuberculosis was most fatal in damp and unsanitary houses. All education would prove futile unless we looked to the improvement of housing conditions.

Mr. Christopher Easton of Newport, R. I., thought it well to take up the economic side of the question, the cost to the community in dollars and cents. Unless this was done someone was sure to come along and tell us of the social waste. Many consumptives were unemployed because of their inability to engage in the struggle for existence.

Dr. J. H. Lowman of Cleveland, Ohio, said that the work in Cleveland had been on the lines laid down in the paper. Ten lectures were written for the workingmen and delivered for two years, and then a small league was organized, then a general tuberculosis dispensary, a tuberculosis charitable organization, etc. In the meantime they had laboratories for the examination of sputa and the sanatorium and hospital worked in harmony. The antituberculosis league was made up of the Young Men's Christian Association, Labor Unions and all that had anything to do with the uplifting of the poor.

Dr. T. J. Jones of Hampton Roads, Va., said that the death rate among the colored people was three times as great as among the white and they did not have the ability, education or money to aid them in resisting the disease. At Hampton Institute they had started a movement to combat this disease and had organized societies all over Virginia. Dr. Jones asked the moral and financial aid of the association.

Dr. George M. Sternburg, U. S. A., said that the death rate from tuberculosis among the colored people of Washington was exceedingly high. The death rate from this disease among the white population compared favorably with any city in the country. In the slums where the colored people lived the houses were unfit for habitation. The problem had been how to suitably house these people. One organization had been formed for the purpose of building sanitary houses and a company recently formed gave a flat of three rooms, every room light and properly ventilated, with hot and cold water in the bathroom, for seven dollars per month. They had raised $30,000 and built 20 houses, all of which were occupied. He thought that building proper homes was the fundamental thing in combating this plague.

Dr. Coon of Worcester, Mass., thought that much could be done in the prevention of tuberculosis during early life and in school days. One could give children right ideas about enlarging the chest capacity, breathing exercises, the right way to live, etc., which would enable them to ward off tuberculosis. Some days he made as many as seven addresses for the purpose of keeping up this instruction.

Dr. Antonio Stella of New York said that the prevalence of tuberculosis among the Italians in this country must be explained as its existence among the negro race was explained, the city life and all that it implied. The lectures given under the auspices of the Charity Organization Society had done much good. At first they were only attended by 10 to 15 persons, but this year there had been as many as 300 who attended these lectures in the public schools.

Dr. Travis of Chattanooga, Tenn., said that he was interested in the remarks made by Mr. Devine on account of the prevalence of tuberculosis among the colored population. The negro needed education as well as money, but the education should come first. He said that the negro living in the country very seldom had tuberculosis, but in the cities the disease was becoming more and more frequent.

Dr. John S. Fulton of Baltimore said that he was particularly interested in the problem of locality. He said that it had been brought out that the mortality in the city of Washington was 323 and this seemed to show reason for alarm. The total mortality among the whites was 138 and the average mortality about 297. To diminish the tuberculosis mortality in Washington it might be well to empty the departments of young people.

Dr. S. A. Knopf of New York said that he had recently had his first conference with prominent citizens of the negro race and they admitted that before liberation from slavery the mortality from tuberculosis was almost *nil*, while it was now excessive. They also admitted that this condition was due to bad housing and bad living. They kept late hours, being employed as waiters, hall-boys, etc., and living in a very unhygienic manner. He thought we could not do much for the negro without intelligent negro help. The intelligent negro should help in educating his own people. Whenever he was called on to lecture to school children he always gave them what he had on the prevention of tuberculosis alphabetically. We should remember that the scrofulous and tuberculous child might become a consumptive adult. He thought the Charity Organization Societies of the various States and cities were more suited than any other organization to take up this work.

Mr. Edward T. Devine of New York in closing the discussion said that the title of his paper might be interpreted as a discussion on the relative functions of national, State and local societies for the study and prevention of tuberculosis. He thought every committee should have some sort of national beginning. The national association should formulate rules for the local bodies to follow and local organizations should receive encouragement wherever found. There should be gathered together such information as Dr. Sternberg and Dr. Jones had given. The National Association should put this in such shape as to be useful to those who needed such information. In large States like New York, Illinois, or Pennsylvania there should be several divisions, each of which should work out its own local problems. Medical bodies should become united in framing symmetrical laws to govern their work in all national, State and local bodies and should cultivate such relationships as would enable them to work together in more harmony.

ASSOCIATION OF AMERICAN PHYSICIANS.

Twentieth Annual Meeting, Held in Washington, D. C., May 16 and 17, 1905.

(Special Report to the Medical Record.)

(*Continued from page 796.*)

WEDNESDAY, MAY 17—SECOND DAY.

Consideration of Proteid Diet with Special Reference to the Distribution of Amidonitrogen, Diaminonitrogen and Monaminonitrogen Therein.—Drs. L. F. Barker and B. A. Cohoe of Chicago presented this paper which was read by Dr. Barker. The well-known variations in tolerance of the same individual for different kinds of proteid food, made it desirable to search for a cause in the chemical constitution of the foods themselves. Though studies of the nitrogen content and purin holdings in various articles of proteid diet had been undertaken, the distribution of the various forms of nitrogen had not hitherto been investigated. They had applied the method of Hausmann, as improved by Osborne and Harris and by Gumbel, for such analysis. The amidonitrogen, meloninnitrogen, diaminonitrogen, and monaminonitrogen in various cuts of beef, veal, and pork, in liver, in fish, and in chicken, had

been determined and the paper dealt with the results of these studies. Charts were exhibited showing the aminoacids of the proteid molecule, many of which were already known as tyrosin and leucin in phosphorus poisoning. The study of albumin showed how it differed in composition. Eight aminoacids had been synthetically united in a chain and they believed that possibly in time, if they kept on the present work, they might ultimately be able to produce an artificial albumin. In fact, they believed that five years from now they would be able to produce synthetically every type of albumin now known. It should not be inferred from what was stated that this had anything to do with life itself. Albumin was built up of different numbers and kinds of building stones, so to speak; arginin, for instance, in some molecules represented 80 per cent., while in others 40 per cent., 20 per cent., and even 1.8 per cent., and there was both a quantitative as well as a qualitative difference. Egg or serum albumin contained 17 or 18 different varieties of these aminoacids. This gave them a clew to the study of proteid foods and they thought it was very important to find out the constitution of the individual albumins as found in meats, fish, etc. Hausmann had introduced the preliminary survey showing different kinds of bodies to be found in complex albumins and had been of great service to them in their own investigations, especially after having been improved on by Osborne, Harris, and Gumbel. Charts were presented showing the nitrogen distribution expressed in percentages of total nitrogen in veal cutlets, pork chops, sirloin, tenderloin, neck, etc., showing amidenitrogen, melandoidinnitrogen, diaminonitrogen and monaminonitrogen. So far they could say nothing regarding the practical value of their work. Chemical methods no doubt were to be of great help to them but chemistry would not solve everything. In gout aminoacids appeared in the urine and the presence of this acid might prove to be of greater importance than the presence of uric acid. Again in phosphorus poisoning leucin and tyrosin appeared in the urine and it was reasonable to suppose that other aminoacids might appear in the urine. The investigations showed that the distribution of these acids was greater than generally supposed.

Dr. Victor C. Vaughan of Ann Arbor, Mich., held that every cell, whether bacterial or a cell body, was a distinct chemical compound. He said that if one took a cellular substance and purified it and estimated the amount of amido, monamido and diamido acids you would get the same whether it was 1 per cent. or 5 per cent. acid. These cells were definite chemical molecules. Therefore, if the cell was to be so regarded, impairment of cell function due to the introduction of abnormal groups into the cell, an abnormal arrangement of the groups in the cell, etc., made it possible that man might sometime or other be able by his researches to make internal medicine thoroughly scientific.

The Chloride Exchanges in Three Cases of Chronic Nephritis with Reference to the Dechloridation Treatment.—Drs. O. A. J. Kelly and Charles A. Fife of Philadelphia presented this paper which was read by Dr. Kelly. Three cases of chronic nephritis were subjected to the most careful scrutiny as regarded the diet, special reference being made to the chloride intake and the chloride output. Bread made without salt, meals eaten without salt, etc., were given, and the relationship was studied between such chloride retention and edema, the effect upon the edema and the other phenomena of nephritis of an almost salt-free diet, and with the administration of sodium chloride. They concluded that as regarded the prognosis, sodium chloride was of value in indicating the severity of the lesions. In many cases of nephritis a salt-free diet was of value. The injection of saline solution, especially in cases of nephritis, as so often practiced to-day, was to be deprecated because of the harm which resulted.

Chloride Retention in Nephritis.—Dr. Joseph L. Miller of Chicago presented this paper which was read by Dr. Frank Billings. In cases of moderately severe nephritis associated with edema, the administration of sodium chloride might be followed by chloride retention and symptoms might develop which resembled uremia. There was a poor elimination of sodium chloride in nephritis. An increase in edema, increase in albumin, uremic symptoms, etc., followed the use of large amounts of sodium chloride. Edema was partly the result of lessened perspiration due to increased molecular concentration of body fluids (Kovesi). The results were given in two cases of acute and six of chronic parenchymatous nephritis; one case of secondary contracted kidney; one case myocarditis; and in four normal individuals.

Dr. Alfred Stengel of Philadelphia spoke of two cases reported by Dr. Kelly which he had had under observation and whose improvement he believed to be due to the general improvement. He also reported the case of a man, 36 years old, who had had an acute nephritis eight or ten years years ago, and repeated attacks of failing compensation of the kidneys since. This patient developed a high grade of arteriosclerosis and the highest blood pressure Dr. Stengel had ever seen. He had the usual periodical headaches and the blood pressure showed a systolic pressure of 280 mm. of mercury and 200 mm. during diastole. The patient said he had been an inordinate salt eater. After reducing the salt ingested he quickly began to improve; the improvement was remarkable not only on account of the headaches, but also in regard to the marked reduction of the blood pressure. Dr. Stengel thought that possibly the milk in nephritis might be so productive of good because of the lack of the chlorides.

Dr. F. P. Kinnicutt of New York said that during the past two years he had been using salt for its supposed diuretic effect and with good results.

Dr. D. L. Edsall of Philadelphia thought the administration of sodium chloride might be of limited diagnostic value even though it might be of prognostic value.

Dr. S. J. Meltzer of New York said he was under the impression that the giving of sodium chloride was simply a factor in the process of osmosis; a certain amount of salt was necessary in order that osmosis could take place. In diabetes there was sugar in the tissues and the fluids were attracted, giving rise to intense thirst. By washing out the stomach one got rid of a certain amount of chlorides and therefore one factor for osmosis was eliminated and improvement followed with reduction of the polyuria. If this was so he asked why the same should not hold good by giving salt-free food.

Dr. R. C. Cabot of Boston asked whether our present knowledge told us when we should discountenance the giving of excessive amounts of salt in a perfectly well person.

Dr. George M. Sternberg, U. S. A., said that a medical man of the army was so thoroughly convinced that the taking of so much salt produced certain troubles that he advised persons not to partake of it.

Dr. A. Jacobi of New York asked what the experience had been thus far of giving salt-free food to epileptics.

Dr. Joseph Collins of New York said that two years ago he took 25 epileptics who were under daily observation and the majority of whom had had various methods of cure tried. They were given a diet of salt-free food. There were 24 cases who showed during the two years a reduction of 38 per cent. in frequency and severity of their epileptic attacks, *i. e.*, a little more than 33 1-3 per cent. Recently he had taken five cases seen in dispensary work; four out of the five cases had their attacks diminished to 50 per cent. There seemed to be no doubt that salt-free diet was a very important element in the treatment of epilepsy. He believed a normal individual could take as much salt as he wished, so long as he had no kidney or vascular disease up to a certain time. After the kidneys contracted and the blood vessels became brittle, etc., the patient could not take sodium chloride in such large quantities.

Dr. James Tyson of Philadelphia referred to Dalton's

textbook on Physiology and what was stated there regarding the condition of the cattle when deprived of their salt.

Dr. A. O. J. Kelly of Philadelphia said that the intake and output should be equal in normal individuals. Widal and Javalle had suggested giving cows food deprived of salt, in order to possibly obtain a milk that would be particularly valuable for nephritic cases.

The Toxicity of Bile.—Drs. S. J. Meltzer and William Salant of New York presented this communication, reporting briefly some results obtained in a series of experiments of the various toxic aspects of bile upon animals, especially frogs. It was demonstrated that bile contained two elements, one a tetanizing and the other a paralyzing element. They were antagonistic to each other. The symptoms produced should be grouped into those belonging to the motor sphere (convulsions and paralysis), the sensory sphere (pain and anesthesia), and conscious sphere (mania and coma). All three phases have either convulsions, or pain, or the exhibition of mania on one hand and, on the other, coma, paralysis, or anesthesia. An increase in the excitability on the one side or a depression of the other, might be produced by a number of substances as, for instance, strychnia to excite or morphine to depress. Yet no one substance produced exclusively one excitation; strychnine might depress as well as excite; to be normal there should be a balance, or a neutralization in one or the other direction, and upon this balancing depended life.

The Nature and Origin of Cholemia and Uremia.—Dr. S. J. Meltzer of New York reviewed the various theories of the nature and origin of cholemia and uremia and he presented his own theory, based partly upon the experiments reported in the foregoing paper.

Dr. James Ewing of New York, Dr. S. Solis Cohen of Philadelphia, and Dr. Carroll, U. S. A., discussed these papers.

Xanthelasma and Chronic Icterus.—Dr. T. B. Futcher of Baltimore read this paper, which was based upon the observations of three cases of multiple xanthomata in patients with chronic icterus, who were admitted to the medical wards of the Johns Hopkins Hospital, Dr. Osler's service. All were women, their ages ranging from 39 to 42 years. In two the jaundice was occasioned by gallstones, and in the third by hypertrophic cirrhosis of the liver. In one case, there was eventually spontaneous disappearance of the xanthomata. The causal relationship between the jaundice was discussed as well as the cutaneous and visceral distribution of the xanthomata. The histological appearance was described. Although the etiology was not understood, it was supposed to be due to some toxin developed in the liver and circulating in the blood.

Dr. A. Jacobi of New York asked regarding the yellow spots so often observed in the upper eyelid in women, and asked if they were the same as found in xanthelasma. He always thought they were due to a fatty degeneration, prematurely developed.

Dr. Futcher thought they were somewhat identical, although they were more of the fibrolipomatous type rather than a true xanthomata in connection with jaundice.

A Report of a Case of Lymphatic Leukemia in a Child of Three Years.—Drs. John Lovett Morse and Harry C. Low of Boston presented this paper, which was read by Dr. Morse. The duration of the disease was five months. The blood picture was suggestive, but not at all characteristic for four months. Lymph nodes, removed at the end of three months, suggested a sarcomatous growth, and did not justify the diagnosis of leukemia. A node, removed at the end of four and a half months, showed an enormous proliferation of the lymphoid cells and characteristic appearance of lymphatic hyperplasia. The chief peculiarities of the case were the atypical blood and lymph nodes at the early examinations. He believed this history should serve as a warning not to arrive at any definite diagnosis in such cases.

Dr. Forchheimer of Cincinnati recorded a case in which there was a great rapidity in development. A child of eight months suffered from a staphylococcus sore throat, which was followed by swelling of the lymphatics, parotids, etc., and six weeks later a blood count was made. It gave 8,200 leucocytes, of which 97.6 were lymphocytes; eight weeks later there were 88,800 leucocytes, of which 98 per cent. were small lymphocytes. A short time before the child died there were 151,000 leucocytes with 99.6 per cent of lymphocytes. The spleen was slightly enlarged, and all the glands in the body could be felt. No postmortem was obtainable. The child lived ten weeks.

Dr. L. F. Barker of Chicago, Dr. W. S. Thayer of Baltimore and Dr. William H. Welsh of Baltimore discussed the paper.

A Lantern Slide Exhibition Demonstrating the Stages of Calcareous Degeneration.—Drs. J. George Adami and Oskar Klotz of Montreal made this interesting demonstration.

Experimental Arteriosclerosis with Demonstration of Specimens.—Drs. Richard M. Pearce and E. MacD. Stanton of Albany presented this paper, which was read by Dr. Pearce. It comprises a study of the changes produced in the large vesels of the rabbit by repeated intravenous injections of adrenalin, with demonstration of the gross specimens and a description of the histological changes, together with a discussion of the manner in which adrenalin produced such changes. Rabbits received two or three minims of adrenalin at a dose, receiving the injection five or six times a day; after ten or twelve days no gross changes were to be noted, but histologically there appeared focal degenerations affecting the inner and muscular fibers. The next change occurred in the elastica, mechanical, no doubt, in nature. The fibres became swollen, elongated, and lost their twisted appearance, and later became fractured. After four or five weeks 20 or 25 drops a day could be given without notable effect. The condition found then was analogous to arteriosclerosis as found in man. The arteries could be cracked between the fingers and were filled with calcareous particles, irregular plaques of calcification. The lesion seemed to begin in the media with a compensating process in the intima. What caused the lesion he could not say.

Phlebosclerosis.—Dr. C. F. Martin of Montreal read this paper, in which he stated that cirrhosis of the veins had been recognized for some time, although there was but little reference to it in literature. The veins of the lower extremity were those most frequently involved, especially the internal and external sapheni. He presented a diagram showing the condition in 14 cases. One of the most interesting features was that it was most common in the young, the ages all being below 35 years. There was, too, an absence of arteriosclerosis. This was a very common affection, and in over 60 per cent. of the cases in adults they were able to detect it clinically. It was more commonly met with in the male. In the majority of the sections examined there were no evidences of inflammation, and he believed the condition might be regarded as functional from mechanical causes, such as a strain, exercise, etc., anything that resulted in lack of support.

Drs. William H. Welsh of Baltimore and S. J. Meltzer of New York discussed this paper.

Observations on Metabolism in a Case of Acute Leukemia and a Case of Purpura Hemorrhagica.—Dr. D. L. Edsall of Philadelphia read this paper. The case of leukemia showed remarkable tissue construction, and the same was true of purpura hemorrhagica. The conditions in the latter case indicated that hemorrhage was not an important feature in causing the remarkable nitrogen loss in either class of cases. There were also certain differences in the metabolism in the two cases, indicating differences in the character of the conditions producing the tissue loss, an additional evidence that hemorrhagic conditions were of varied nature.

The Influence of the X-Ray on Metabolism in Leukemia.—Drs. John H. Musser and D. L. Edsall of Philadelphia

presented this communication, which was read by Dr. Edsall. Two cases were studied, one of which responded to the *x*-ray treatment by rapid improvement; the other was uninfluenced and was soon fatal, though there had previously been improvement on *x*-ray treatment. In the first case there was, immediately after starting the *x*-ray treatment, a remarkable increase in the excretion of nitrogen, phosphorus, uric acid and xanthin-bases; in the fatal case there was at first a slight rise, but the excretion soon fell back to the previous point or below it, and with the approach of death the excretion became very low. This seemed clear evidence that the *x*-ray acted not through a direct effect, but through an influence upon some body process, probably autolysis. It was stated that radium also increased autolysis. The *x*-ray undoubtedly at least temporarily profoundly influenced these cases, but might have a dangerous effect. In a case of pernicious anemia the use of the *x*-ray made the condition markedly worse. He believed that it was very necessary to determine the dosage of the *x*-ray and not to use it regardlessly, as many were now doing. It had been used on two severe cases of diabetes without effect. It had been used, too, in an unresolved pneumonia and with marked benefit.

Dr. L. F. Barker of Chicago was especially interested in the results Dr. Edsall had obtained and in the speed with which the reactions had occurred. It could not be largely a matter of catalysis. The introduction of the consideration of catalysis would be very helpful in work on metabolism.

Chronic Acetanilid Poisoning.—Dr. D. D. Stewart of Philadelphia made a report of a recently observed case, the symptoms and blood condition of which at first suggested pernicious anemia. The patient was discovered to have taken daily for several years considerable quantities of a secret nostrum, the chief ingredient of which was acetanilid. Rapid improvement followed the withdrawal of the drug.

A Brief Report on Recent Researches in the Writer's Laboratory on Bacterial Toxins and Immunity.—Dr. V. C. Vaughan of Ann Arbor read this paper. He said that when bacterial cellular substances were heated at 78° with a dilute solution of sodium hydrate in absolute alcohol, the cell substance was split into two portions. One portion was soluble in absolute alcohol and contained the poisonous group of the cell. The poisonous group had been studied, having been obtained from the colon, the typhoid and the anthrax bacillus and the micrococcus of pneumonia. A similar, if not identical, poisonous substance might be obtained in the same way from certain proteid bodies, such as egg albumen and peptone. Animals might be immunized with this toxic body. However, the immunity thus induced was not specific, or at least not markedly so. The part of the cell substance insoluble in alcohol was soluble in water, and with this a specific immunity could be obtained. This second portion also contained a hemolytic body. The kinds of immunity obtainable with the above-mentioned split products, also the nature of the hemolytic substance, was discussed.

Drs. William H. Welsh of Baltimore and S. J. Meltzer of New York discussed this paper.

Report of a Case of Acromegaly.—Dr. Charles L. Greene of St. Paul read a paper on this subject and reported a case, which had been associated with symptoms of myxedema. He reported the progressive changes in this case, which was under observation for a period of eight years. In 1901 the patient presented the usual symptoms of acromegaly (1) a condition of the hands, neck, and shoulders which were not to be distinguished from myxedema; (2) the predominating hyperthrophy of the upper jaw with marked separation of the teeth; (3) bilateral chronic synovitis of the knee joints. The first symptoms, noticed by the patient in 1896, consisted of progressive enlargement of the hands and feet, and changed facial outline and expression. The symptoms steadily progressed until 1901, when there was noticed an enlargement of the clavicles, scapulæ, and ribs, which progressed steadily up to the present time. During the last twelve months the patient had shown a decided stoop and evidences of progressive weakness, without pain or disturbances of special sense or of the general nervous system. The skin of the face and ears were much hypertrophied and thrown into deep furrows. The nose and eyelids were originally tumid, but much less so at the present time. The upper jaw had not increased in size since 1898. The larynx and cartilages, originally hypertrophied, showed no further change, and radiographs demonstrated the extent of the bony enlargement of the extremities. When originally seen and during the period of myxedematous manifestations the thyroid gland was enlarged, though soft. At the present time the myxedematous changes were entirely absent and the thyroid gland was apparently normal in size. First disappearance of the myxedema followed the persistent administration of thyroid tablets, showing a tendency to recurrence whenever they were discontinued. No treatment had been necessary during the past eighteen months. The following points of interest seemed to justify the report: (1) Coincidence of symptoms of myxedema and undoubted acromegaly, with enlargement of the thyroid gland; (2) disappearance of all symptoms of myxedema associated with the shrinkage of the enlarged thyroid and under the administration of the thyroid tablets; (3) the shifting of the site of abnormal bony growth; (4) the long period of observation.

The Nature of Cirrhosis of the Liver.—Dr. A. O. J. Kelly of Philadelphia said that a study of cirrhotic livers, with special reference to the changes in the parenchymatous tissue, suggested that cirrhosis of the liver was primarily a degenerative process involving the parenchyma, followed not only by hyperplastic changes in the connective tissue, but also by reparative alterations on the part of the parenchyma. In speaking of the size of the liver, he said that observations conducted at the German Hospital on from 110 to 115 cases in which a diagnosis of cirrhosis of the liver had been made, in but 40 per cent. of them the liver was enlarged.

Dr. Richard M. Pearce of Albany presented illustrations showing experimental work in cirrhosis produced in dogs.

Pathological Anatomy of Exophthalmic Goitre.—Dr. W. G. MacCallum of Baltimore said that in recent papers on this subjject it had been claimed that there were no specific and definite anatomical change in the thyroid, but there were changes such as had been brought out by Halsted, a compensatory hypertrophy of the thyroid, as shown in dogs. The changes were not always of equal intensity. The parathyroids had been found to be practically normal in nine cases in which he had been able to examine them. The parathyroids had nothing to do with exophthalmic goitre.

Election of Officers.—*President,* Dr. Frank Billings of Chicago; *Vice-President,* Dr. F. P. Kinnicutt of New York; *Secretary,* Dr. Henry Hun of Washington; *Recorder,* Dr. Solomon Solis Cohen of Philadelphia; *Counselor,* Dr. T. Mitchell Prudden of New York.

Elected to Membership.—Dr. A. B. MacCallum of Toronto, Dr. David Riesman of Philadelphia, Dr. Adolph Meyer of New York, Dr. J. L. Miller of Chicago, Dr. R. H. Babcock of Chicago, Dr. Thomas McCrae of Baltimore, and Dr. S. S. Adams of Washington.

Elected to Associate Membership.—Dr. J. D. Steele of Philadelphia, Dr. Joseph Sailer of Philadelphia, Dr. Joseph A. Capps of Chicago, Dr. Henry Christian of Boston, Dr. A. E. Taylor of San Francisco, Dr. L. A. Connor of New York, and Dr. Theodore Janeway of New York.

Health Insurance Sanatoria in Germany.—Some of the German health insurance companies have found it a paying investment to establish sanatoria for the care of their consumptive policy holders.

Philadelphia County Medical Society.

At a stated meeting, held April 26, Dr. W. S. Newcomet exhibited a group of cases, illustrating the therapeutic effects of the *x*-rays. Dr. Carl Beck of New York read, by invitation, a paper entitled "The *X*-Ray on the Diagnosis of Tuberculosis of the Bones and Joints." He pointed out the great utility of this method of clinical investigation and illustrated his remarks by numerous photographs and skiagrams. He also adverted briefly to methods for treating the disease comprehended by his paper. Surgical intervention is frequently necessary, sometimes as a primary procedure, at other times to remove the products of disease itself cured by *x*-ray or other treatment. Dr. G. E. Pfahler presented a communication entitled "The *X*-Ray in the Diagnosis of Pulmonary Tuberculosis." He stated that this means of recognizing the presence and the extent of tuberculous disease of the lungs is superior to every other, and is particularly valuable as a means of comparing the progress or retrogression of the lesions. Exposures need not occupy more than from five to twenty seconds, the patient meanwhile holding the breath in order that the diaphragm shall be kept at rest. A number of illustrative negatives were illuminated, showing the situation, the distribution and the character of the lesions in a way admittedly beyond demonstration by the ordinary means of physical diagnosis. Dr. W. S. Newcomet read a paper on "The *X*-Ray in the Treatment of Superficial Tuberculosis." He considered especially tuberculosis of the skin and the glands, and cited cases exhibiting the good results of the treatment. The expense of treatment can be diminished by utilizing a cabinet with four compartments, permitting that number of patients to be exposed to the tube at a single sitting. Dr. Henry K. Pancoast read a paper entitled "The *X*-Ray in the Treatment of Deep-Seated Tuberculosis." He reported several cases of laryngeal tuberculosis in which improvement attended *x*-ray treatment, and also a case of peritoneal tuberculosis in which a similar result was obtained. The discussion was participated in by Drs. W. L. Rodman, S. Solis-Cohen, Judson Daland, J. B. Shober, M. K. Kassabian, and S. Mason McCollin.

Chicago Medical Society.

At a regular meeting, held April 12, "Surgical Anesthesia" was discussed. Dr. H. D. Peterson spoke of ether or chloroform, methods of administration, dangers, and after-effects. He stated that the relative value of these two anesthetics depended upon the safety. Safety was measured by the action of the drug and experience of the anesthetist. Chloroform being more depressant and toxic was less safe than ether. Statistics had proven the death rate to be higher with chloroform than with ether. The choice of anesthetic was to be decided by the condition of the patient and experience of the administrator. There were few contraindications to ether, more to chloroform. Heart disease, shock, and prolonged operations were urged against chloroform. Chloroform was unsafe in the hands of the unskilled. The author recommended the closed method for ether, the open for chloroform. Each should be commenced by slow application. A minimum amount should be added after stage of surgical anesthesia was reached. As to the dangers, they were few if ether was used. Death from ether was usually due to inattention or carelessness of the anesthetist. Warning was always given. Chloroform was sudden in its action; little or no warning was given. Close watch of the patient was necessary when chloroform was used. Recovery varied with the dose given. A minimum dose was followed by the quickest recovery. The patient should be watched until conscious enough to clear his own throat of mucus. As to after-effects, vomiting was often prevented by allowing the inhalation of vapor of aromatics, vinegar or acetic acid. Salt solution per rectum or by hypodermoclysis aided in the rapid elimination of a general anesthetic. Dr. A. E. Halstead discussed "Spinal Anesthesia." The objections to the use of spinal cocainization that were usually made were stated as (1) that there were immediate and remote dangers, which were considerable; (2) that it was uncertain in its action, both as to producing surgical analgesia and as to its duration; (3) that attempts at introducing cocaine sometimes failed; (4) that unpleasant after-effects resulted. The technique employed by the author was that followed by Tuffier. The steps were mentioned. In operations upon the lower half of the body, when, from kidney, lung, or heart disease, a general anesthetic was dangerous, and where infiltration anesthesia or analgesia from neural injections was not possible, spinal analgesia could be employed. In strangulated hernia or intestinal obstruction from other causes, and perforations, where considerable time might be required, thus contraindicating the use of local anesthesia, it could be used. Spinal cocainization was an ideal method of securing analgesia, first, because the patient remaining conscious was not so likely to drown in fecal vomit; second, because the shock from the puncture was practically *nil*. In traumatic surgery of the lower extremities, the use of spinal cocainization blocked the reflexes and eliminated the great risk of shock. In amputations about the hip, when the shock from the operation was generally severe, and often fatal, after cocainization of the cord the amputation might be performed without any change in the pulse rate. In this class of operations if, for good reasons, unconsciousness was essential, as it sometimes was, a small amount of ether and chloroform might be administered to secure this end. The spinal cocainization insured the required analgesia. The author believed that spinal analgesia was contraindicated in all cases in hysterical women, and young children, and in the insane. It should be used only when its action could be explained to the patient, and thus cooperation be secured. He did not consider any ordinary heart lesion a contraindication to its use. Dr. Weller Van Hook discussed "Nitrous Oxide Anesthesia." No modern hospital was complete in its equipment without apparatus for administering nitrous oxide gas. Inasmuch as gas alone produced a lethal asphyxia in from three to five minutes, oxygen must be utilized when cyanosis became pronounced. The addition of about ten per cent. of pure oxygen made it possible to continue anesthesia with nitrous oxide gas a comparatively long time without much risk. Unfortunately the combination made necessary a complicated and bulky apparatus. Furthermore, the use of the two gases was rather difficult until the anesthetizer, by practice, had become expert. This difficulty rendered it next to impossible to entrust to hospital assistants, whose term of anesthetic service was brief, so complicated a duty. If, however, oxygen was admitted to the mask with air from time to time as it was needed, the apparatus demanded could be simplified to a practical point. The apparatus which the writer used for this purpose was the ordinary dental outfit, the face-piece being that of Harrington. The portability and convenience of the steel bottles containing the liquefied gas and the inhaling apparatus left but little to be desired in hospital practice. Instead of the 250-gallon bottles used in institutional work, a 100-gallon bottle, weighing approximately nine pounds, could be used in private practice. It was many years ago that the idea was conceived of using nitrous oxide to abolish consciousness, followed by ether to maintain that state. It was early discovered that if air was admitted to the mask after nitrous oxide anesthesia had been induced, the patient would recover consciousness to such a degree that the ether anesthesia could be inaugurated only with difficulty, the patient often struggling violently. The ideal way of changing from one to the other of these anesthetics was by gradually adding ether vapor to the inhaled gas. The writer had had made a simple cap to contain a piece of gauze saturated with ether, which could be applied to the nitrous oxide apparatus at the moment of making the change, so that no air would be admitted to the mask until after the patient had inhaled the desired amount of ether. With this apparatus the writer had had very satisfactory results.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending May 20, 1905:

	Cases	Deaths
Measles	700	10
Diphtheria and Croup	345	36
Scarlet Fever	221	13
Smallpox	1	1
Chickenpox	152	.....
Tuberculosis	417	155
Typhoid Fever	28	9
Cerebrospinal Meningitis	69	72
Typhus Fever	.....	.....
Yellow Fever	.....	.....
Cholera	.....	.....
Totals	2,023	296

Sterilization of Cutting Instruments.—H. A. Royster draws a comparison between the cutlery of the older surgeons and those of the present day. He says that it is an open question whether the marked excellence of the earlier instruments was due to superior material and workmanship, or to less wear and better care. Probably both factors are concerned. In former times, operators being ignorant of the origin of sepsis, had instruments that would cut. All of their troubles came after operation, none before. With modern surgeons the reverse is true. The writer declares that all methods now in vogue for sterilizing instruments dull the edges of those intended for cutting purposes. The writer has recently sent to a number of operators in different parts of the country the following inquiries: (1) How do you sterilize your knives and scissors? (2) What method has the least effect in dulling their edges? The answers as to the scissors were practically unanimous. They are boiled along with the other instruments. Various answers were received in regard to the knives. A large proportion of surgeons, however, are abandoning the sterilization of knives by boiling, presumably because they find that it unfits them for use. The writer thinks that we are warranted in drawing the following conclusions: Knives can be safely sterilized by chemical and mechanical means without the use of heat in any form. The majority of American surgeons are using carbolic acid, or alcohol, or both. Immersion in 95 per cent. alcohol has the least, and boiling the most effect in dulling the edge of a knife.—*Annals of Gynecology and Pediatry.*

The Prevention of Apoplexy.—T. Clifford Allbutt says that although the very term "apoplexy" signifies a "stroke as if from the stars," nevertheless the conditions which give rise to it are the result of slow development. The event is surprising to the unwarned only. It signifies physical modifications of long duration and gradual progress. The writer believes that in a large number of cases of sanguineous apoplexy the kidneys are not granular; and if in some cases they are fibrous, there is nothing of the nature of chronic Bright's disease. The evidence of this statement is presented by the condition of the secreting structures of the tubes which show no foci, or traces of past foci, of degeneration or necrosis. The writer in this paper does not consider the cases associated with Bright's disease. In a case of apoplexy the brain appears healthy, the heart hypertrophied, and the arteries spoiled. The phenomena lie in the mechanism of the circulation. In a simple case the heart presents no primary changes. The changes are altogether secondary. The arteries are diseased—atheromatous or sclerosed. They have at last burst because they have sustained gradual injury. They have been subjected to the mean pressures of age and also to the augmenting mean pressures of a reluctant peripheral circulation. The cause of the embarrassed circulation must consist either in a narrowing of the calibres of the arteries over an extensive area or universally, or in an increase of viscosity with excessive friction in the blood itself. The writer believes that the prevention of apoplexy must lie first in the detection of a special tendency to a persistent mean rise. The writer urges that as a matter of routine every adult of the age of forty and upwards should have his blood pressures measured by the best instruments available. This routine should be repeated every five years till the age of sixty, when, if there be no great increase, the danger of apoplexy may be disregarded. If persistent rise of mean pressures is found in any person, the mode of life of the patient must be revised. Regular exercise, abstinence from alcohol, and a great reduction in the intake of food must be ordered. In these cases the regimen and the waters of certain spas, such as Harrogate, Carlsbad, or Marienbad, are invaluable. The readiness of response varies widely in different individuals. —*The Bristol Medico-Chirurgical Journal.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ending May 20, 1905:

INFLAMMATORY DISEASE OF THE UTERINE ADNEXA AND ITS TREATMENT.*

BY H. GRAD, M.D.,
NEW YORK.

IN considering the subject of inflammatory diseases of the uterine adnexa, it may not be amiss to make brief mention of the anatomy of these organs. The Fallopian tubes are two musculomembranous tubes of variable caliber, springing from the upper angle of the fundus of the uterus, and extend outward along the upper edge of the broad ligaments. The tubes communicate with the uterine cavity by very narrow openings, they being largest at their inner ends, the ostium abdominale. The tubes are covered by peritoneum, except at their lower border, where the two layers of the peritoneum come in contact to make up the structure of the broad ligaments. This anatomical arrangement of the peritoneal investment of the Fallopian tubes is of great importance from the pathological point of view, as it explains pathological states of the broad ligament and parametrium, in which the initial infection was that of the tubes. The mucous membrane of the tubes is continuous with that of the uterus. This structure is thrown into numerous folds, especially towards the fimbriated extremities of the tubes. Some investigators have described glandular structures in the mucous membrane of the tube, while other apparently equally as competent investigators, deny the existence of such a glandular structure. The mucous membrane is lined with ciliated epithelium. The consensus of opinion of the best histologists of the present day, is that the mucous membrane of the Fallopian tube is a nonglandular structure. The ovaries are two globular organs, situated on the posterior surface of the broad ligament, and immediately beneath the inner opening of the Fallopian tube. It will be noticed that these organs have no direct external communication, yet by their situation, and especially, connected as they are with the oviducts by the tuboovarian ligaments, they are, necessarily by their very proximity, greatly subjected to deleterious influences coming from without.

It is not intended in this paper to speak of the pathological aspect of salpingitis, and to enumerate the various kinds of lesions of these organs. The object in view is to draw a clinical picture of the cases suffering with salpingitis.

Our present conception of the inflammatory lesions of the uterine adnexa has been of gradual evolution. The atmosphere of mysticism, so to say, in which these pathologic lesions have been shrouded, has gradually cleared somewhat, but we are yet far from knowing all that might be learned about this subject. True, we know that practically all inflammatory lesions of the uterine adnexa are of microbic origin, yet the precise steps of the mode of invasion of the infection, are by no means clear to the pathologist, and why the lesion varies so in different patients. In one patient, for example, a clearly-defined infection of the endometrium does not spread to the tube, while in another case the first evidence of a lesion in the pelvis is the presence of salpingitis. These patients will complain of pelvic discomfort and pain in the groins, where no history of a previous endometrial infection can be obtained; yet we know that the tubal lesions are clearly of microbic invasion. Has the initial infection of the endometrium been so mild as to have caused but little discomfort and escaped the notice of the patient? Then again, why do these lesions remain so chronic in the tube? Why cannot these structures rid themselves of the infection, as other tissues do? Pathologists claim that the nature of gonorrheal infection is such that the deeper structures of membranes are invaded and hence the chronicity of the infection. The chronicity of the lesion, however, is also frequent in infections with pyogenic germs. In cases where the initial infection is quite severe and virulent, the inflammatory reaction rapidly spreading through the uterus and appendages, with abundant pus formation, it is the rule that with the free evacuation of the pus, the symptoms quickly subside and a complete cure results, in a good percentage of cases. Not so, however, in cases where the infection is more insidious. A chronic invalidism of the victim seems the rule. The tubes and uterus appear powerless to rid themselves of the infection, while chronic invalidism, after drainage in the acute infections, is the exception. This is apt to hold good both for the gonorrheal and the pyogenic infection. A thorough evacuation of the purulent material in the acute cases many times results in a prompt cure, while in the more chronic cases nothing short of tubal resection or tubal ablation will suffice.

Investigations have shown that inflammatory diseases of the oviducts are mostly of gonorrheal origin; one pathologist claiming that 70 per cent., others that 47 per cent. of them are of the specific nature. The discrepancy in these figures probably lies in the fact that gonococci are cultivated with difficulty. While it is true that the vast number of cases of chronic salpingitis are of gonorrheal origin, the specific microbe may also be the factor in an acute pyosalpinx; the inflammatory process being just as acute as that initiated by the pyogenic germ. In illustration I shall cite a case coming under observation. A colleague officiated at an accouchement, the patient passing through a normal puerperium. Ten days later the husband of the patient, wandering away from the path of virtue, contracted a specific urethritis and presented himself for treatment. He was earnestly and persistently warned against marital relation with his young wife, but after a few weeks he could not resist the solicitations of his spouse. The result was that she contracted a urethritis and endometritis. The infection spread to the uterus, oviducts, ovaries, and pelvic peritoneum. The inflammatory reaction was of an unusually severe type and the virulence of the infection quite marked. In spite of vigorous therapeutic measures at once instituted, two masses

* Read in part before the Newark Medical Society, January 17, 1905, and before the Passaic Medical Society, February 9, 1905.

appeared in the pelvis on either side of the uterus, with symptoms of profound sepsis. An incision into Douglas's pouch and a thorough evacuation of the pus resulted in a complete cure, followed in two years by a gestation and a normal puerperium. Gonococci could be demonstrated in the pus of the tubes as well as of the endometrium. The tissues in these acute cases rid themselves of the infection quite readily, as has been pointed out by pathologists, the reason being that the personal equation of the patient determines the result of these infections. Specific tissue resistance is the factor. Nor should it be forgotten that in acute processes, the substance called alexin which the modern studies of immunity have brought to light, is produced in quantities sufficient to cope with the infection, while the more insidious infections fail to call into activity these normal defences of the body. Tissue resistance is no doubt an important factor in all acute infections, and this holds good in salpingitis as well. The modern studies in hemolysis will doubtless bring to light important matters in this connection and then we shall have a clearer conception why the severity of the infection of the same species of germ differs so widely in different individuals, and even in the same individual at different times. It is, however, a fact that gonococci most frequently cause a chronic infection in the oviduct and less frequently an acute process; and whereas the acute infection of these structures on evacuation of the pus quickly subsides and is followed by a lasting cure, the insidious infections remain chronic with no tendency towards a cure.

From a clinical point of view, it is practical to consider inflammatory diseases of the oviducts, as (1) the acute, (2) the chronic. In acute salpingitis the usual phenomena of acute inflammations will appear. The mucous membrane of the tube will become congested, round-cell infiltration will take place; the opening of the tubes may or may not become obliterated. If occlusion of the openings does occur, accumulation of purulent material will take place with the formation of palpable masses on one or both sides of the uterus. It is not infrequent to find, in acute affections of the tubes, that one tube is the seat of a large collection of pus, an acute abscess, while the other oviduct shows only a catarrhal salpingitis. This is true of gonorrheal as well as of pyogenic infection. Even in acute salpingitis, although the initial inflammatory reaction is confined to the mucous membrane, it is surprising how intact the tubal epithelium remains. This is of interest from a therapeutic point of view. It may explain why apparently complete cure can result in acute salpingitis after a thorough evacuation of the pus, as was the result in the case cited above. In this case both tubes were the seat of large collections of pus; both tubes were incised, and apparently regeneration of the integrity of both oviducts took place. If the ostium abdominale of the oviduct, the seat of an acute inflammation, closes and the uterine end remains open, the pus may drain off through the uterine canal. A cure of the process may then result; but this is rare; usually such a case will merge into one of chronic salpingitis. If the ostium abdominale does not close, pus may find its way to the pelvic peritoneum, but a localized peritonitis may also result, even if the fimbriated opening of the tube becomes closed. Indeed, salpingitis is always accompanied by peritonitis. If the inflammatory process in the oviducts is purulent the peritonitis will also be of the same character. Serum and pus may collect between the coils of intestines, giving rise to the so-called intraperitoneal abscesses. These abscesses may be single or multiple. They may be located in any part of the pelvis. On account of the increased weight of the inflamed tubes, they gravitate to Douglas's pouch, hence this dependent portion of the pelvis often becomes the seat of the abscess. Into such an abscess one or both tubes may empty, or an ovary may participate in forming some part of the wall of the abscess.

In the pyogenic infections a general peritonitis may have its starting point in the oviduct, while rarely will this be the case with gonorrheal infection. In the event of the tubal openings closing by inflammatory adhesions, the infection may spread through the walls of the tube and pus may escape into the peritoneum through a perforation, or the infection may spread into the layers of the broad ligament. In both events a pelvic abscess will result, but in the former instance we have the abscess in the peritoneum, while, in the latter event, the pus collection is practically extraperitoneal. Clinically, it is impossible to differentiate these two kinds of abscesses before operation. The extraperitoneal collection of pus, usually are the result of infections coming from the cervix and body of the uterus, as in puerperal infections and those following abortion; or the point of inoculation may be a wound in the vagina. It is from these various sources of infection that the old-time pelvic cellulitis results. This process is essentially at first a lymphangitis and finally a pelvic abscess. A puerperal infection, or one following abortion, may also cause salpingitis, the infection spreading by continuity of tissue, and the infective microorganism or their toxines, reaching the peritoneum by way of a patent ostium or a perforation. Both kinds of abscesses may co-exist in the same patient—particularly, if the infection is of puerperal origin. If we exclude those pelvic abscesses resulting from infection of the cervix and vagina and those following abortion, or puerperal state, we shall find that the other pelvic abscesses are of the intraperitoneal type. While it is perfectly true that microbic invasion of a part of tissue and the resulting inflammation and pus collection may occur in three different ways, by continuity of tissue; by the lymphatic channels; and through the blood stream, and pelvic infection is no exception to these three modes of invasion, yet it is an equally stubborn fact that pus collections of the pelvis in the majority of cases, are of tubal origin. In the acute infections of the oviducts, the infective agent may reach the ovary through the escaped purulent material, by way of the patent ostium, and thus an ovarian abscess result, or else the infected ovary by becoming adherent to the tube by inflammatory products, may give rise to the tuboovarian abscess. The ovary may also become implicated in the inflammatory process—the infective agent having reached the organ through the lymphatic system, or the infection may reach the organ through perforation of the tube. That it is possible for the ovary to escape becoming implicated, when inflammatory reaction of the oviducts occurs, must be admitted, but under ordinary conditions, the ovary also suffers in all severe infections of the tubes. In the acute process, however, when the fimbriated openings of the tubes soon close and the infection is confined by the walls of the organ, the ovaries may escape implication. Then again, no germs may reach the ovaries and yet toxins absorbed by the lymphatics may find their way to the organs and cause inflammatory reaction in them.

In the acute as well as in the chronic cases of salpingitis, it is not always possible to differentiate the nature of the infection. In acute gonorrheal salpingitis, when the specific germ can be microscopically demonstrated, the differentiation of the infection is, of course, established, but it must not be

overlooked that although no gonococci are demonstrable in the secretions of the uterus and vagina, the inflammatory process in the oviducts may be of gonorrheal origin. The case may be one of those in which the gonorrheal infection has remained dormant in the tubes, the gonococci having disappeared from the endometrium, vagina and even urinary organs. If foci of infection are visible in the external genitalia or in the presence of a puerperal state, or history of abortion, we may assume that the infection is of pyogenic origin. The practical utility of a differentiation of the kind of infection in acute salpingitis may be of some moment; because we know that the gonorrheal infections frequently remain limited to the tubes and may not call for immediate and vigorous therapeutic measures. One may proscrastinate until the virulence of the infection has expended itself. This is, of course, speaking in general terms—for after all, in the presence of an acute inflammatory process, many factors other than those of the nature of the infection have to be taken into consideration—such as the condition of the patient and the degree of the systemic reaction, etc. We must treat the patient and not the disease. Nor must the fact be overlooked that in acute salpingitis arising after the infection has remained dormant in the tube, tissue resistance is at a low ebb, and only vigorous therapeutic measures will insure successful combat with the infection. The infection having burst into virulence because of lowered tissue resistance, the surgeon must step in to assist the patient in her struggle to overcome the infection. Free drainage is the keynote in the treatment of these acute processes.

An acute salpingitis may finally merge into a chronic process, or the inflammatory reaction may never have had an acute stage, the initial infection having been a comparatively mild one. It may not have been more than the acute onset of a catarrhal process. Systemic reaction may have been entirely absent in these cases, and as a rule great pain and much discomfort are totally lacking. Even intelligent and well-informed patients cannot tell the probable date of the initial infection, so insidious seems the process. The stage of chronic salpingitis having been reached, the patient essentially enters upon the path of invalidism. In some patients the process of chronic salpingitis may cause but slight and transitory disturbance, while in others it will give rise to positive suffering and lasting incapacity. In cases in which the process causes slight disturbance, the patient enjoys long periods of absolute health, and is conscious of only an occasional pelvic discomfort or a painful menstrual period. In these cases pregnancies even occur, followed by a normal puerperium. To all intents and purposes, these patients are well and healthy, except that the oviducts, harboring this mild infection, may become the seat of an acute process with all the dire results of such an outburst of virulence of the infection. It is an interesting query as to how many of these mild cases of salpingitis subsequently become the victims of ectopic gestation. Indeed, it is an established fact that ectopic gestation occurs quite frequently after a variable period of sterility, and this is just what happens in many of these cases. In many instances, marriage is followed by the birth of a child, then comes a variable period of invalidism and sterility, and finally the misfortunes of the victim are capped by a tubal pregnancy. Of course, not every case of tubal pregnancy is the result of salpingitis, but that inflammatory processes in the oviducts do invite such misplaced gestation, cannot be gainsaid. In these mild cases of salpingitis the diagnosis is not readily established, so few are the subjective and objective symptoms. Bimanual examination may not give us enough information to justify a diagnosis of salpingitis. While these mild cases are sufficiently numerous to make the matter of importance to the physician, the vast majority of cases of oviduct infections, of the chronic type, do not fare so fortunately. The victim's condition varies from mild invalidism to total incapacity. The patient is of little use to her family, and her suffering is burdensome to herself. The repeated outbreaks of pain and pelvic peritonitis, the constant backache, the inability to walk and do even light housework, make these patients victims of discouragement. True, the majority of these cases of chronic purulent salpingitis have periods of well being and comparative comfort, yet on the whole, the sum of their suffering is quite considerable, and they are really never entirely well. These patients may not present themselves for examination until years have elapsed since the initial infection, and, indeed, it may be years before subjective symptoms arise to compel them to seek advice. The absorption of purulent material into the circulation, extending over a long period of time finally tells on the constitution. General health is impaired, slight exertion is accompanied by fatigue which passes off slowly. The digestive tract is disturbed and constipation becomes troublesome. They are constantly tired, become irritable and sleepless, suffering with cephalalgia and backache. In those cases of chronic salpingitis in which absorption of purulent material is absent, a constitutional breakdown may also take place on account of the resulting anemia due to the constant loss of blood. These blood losses may be due to metrorrhagia, and to too frequent menstrual periods. It is not uncommon in chronic salpingitis for the menses to extend over weeks, only to reappear after a cessation of 8 or 10 days. Nor is it uncommon for metrorrhagia to be the only symptom of chronic salpingitis, and it may be the cause of constitutional breakdown in this condition.

Metrorrhagia, while significant as a symptom of chronic salpingitis, is also of interest from a diagnostic point of view. Cases with such histories may readily be mistaken for those of ectopic gestations, and vice versa. In chronic salpingitis, as well as in ectopic gestation, we may have metrorrhagia. In both there may be menstrual delays, and palpable masses in the pelvis on one or both sides of the uterus. True, in ectopic gestation there may be a history of sudden attacks of pain as a result of rupture of the gestation sack, but in chronic salpingitis the repeated attacks of pain, due to localized peritonitis, may simulate these. With a given case at hand one cannot be too careful in making a differential diagnosis of these two conditions. Fortunately, both lesions call for the same therapeutic measures and the differential diagnosis is, after all, not so important, speaking clinically. A case illustrative of the difficulties encountered in the differential diagnosis of these two conditions, came under observation, the history being as follows: The patient in the procreative period of life, was taken with sudden abdominal pain soon after retiring, after a hearty meal. Acute indigestion was diagnosticated by the attending physician. The next day, excepting for a slight soreness, she was as well as ever. A second attack of pain occurred the following night, similar in nature to the previous one. I saw the patient in consultation soon after the second attack and diagnosticated an ectopic gestation, because of the disturbance of menstrual history, the tender uterus and a mass in the pelvis to the right of that organ. The alarm of the patient's family grew to such an extent as a result of this diagnosis, that two more con-

sultants were called in. One of them agreed to the diagnosis of ectopic pregnancy, while the second one very justly raised the question of chronic salpingitis. The timely expulsion of a uterine decidua, which always forms in ectopic gestation, decided the question, and an abdominal section confirmed the diagnosis of ruptured tubal pregnancy.

It is still problematical to know to what extent the constitutional breakdown of patients suffering with chronic salpingitis is due to the gonotoxins absorbed. As far back as 1887 Charcot observed deleterious influences of the gonococcus on the nervous system. Since then numerous investigations have confirmed that observation. It is well known to-day that gonotoxins may cause alterations in any tissue of the body—the nervous system not excluded.

As mentioned before, salpingitis is always accompanied by peritonitis, which may be very mild or very severe. It is almost universally of localized type, though in the virulent infections of the oviduct a general inflammation may follow. The accompanying peritonitis introduces a new factor in the process, namely, adhesion of the oviducts to the intestines, omentum, pelvic peritoneum, broad ligament, ovaries, uterus, and bladder, as well as the rectum. Indeed, any pelvic tissues or organs may become matted together by inflammatory adhesions in the course of salpingitis. The matting together of parts and organs is a conservative process on the part of nature, to limit the infection and shut it out of the general peritoneal cavity. Adhesive peritonitis may thus bind the tube to any part of the pelvic wall or contents. In a recent case of total ablation for double tubal disease, it was a curious sight to see the two tubes adherent to the fundus of the uterus, outlining clearly the figure eight like a coiffure. On top of the inflamed tubes numerous coils of intestine were adherent, with the omentum tucked in here and there. This patient experienced an unusual amount of pain and had been an invalid for two years, much of this time being spent in bed. The tortuosity of the tubes with adhesions is the characteristic appearance of the pathologic lesions. It happens thus that in the acute process the pus collections may be found between the coils of intestines and the purulent material may break into the intestine, bladder, rectum, or uterus, and thus escape externally. In the chronic condition, especially those initiated by the gonococcus, the inflammatory process is confined to the oviducts alone, but with numerous adhesions to the ovaries and any pelvic tissue or organ—one or all. Indeed, the pelvic cavity may become shut off entirely from the general peritoneal cavity.

The symptoms of salpingitis vary according to the stage of the disease, the severity of the inflammation and the virulence of the infection. In the acute cases we first have the symptoms of a localized peritonitis. There are present systemic reaction, prostration, pain in the pelvis and lower part of abdomen. The patient lies in bed in a position that insures the greatest degree of immobilization of the pelvic organs. This position is that of dorsal decubitus, with the knees drawn up. Respiration is costal, and the facial expression is anxious. The abdominal muscles become stiff, but not as boardlike as in pathologic processes of the abdominal organs. The recti muscles become boardlike only when the general peritoneal cavity becomes invaded. Tympanitis, however, becomes evident quite frequently in inflammatory diseases of the pelvis. Constipation is often encountered, although diarrhea may exist at the outset of the disease. Not alone are there pains in the pelvis and lower part of the abdomen, but the patient may complain of pains radiating down the thighs or confined to the small of the back, and quite severe in character. Urination may be quite painful and retention of urine is common. The gastrointestinal tract may be disturbed and at the onset of the disease the nausea and vomiting may be quite troublesome and persistent. As more and more of the peritoneal surface becomes invaded the symptoms increase, tympanitis becomes more marked, and the suffering of the patient augmented. It is not infrequent to find that the pain in these cases, which is essentially that of a peritonitis, is distinctly of a paroxysmal type. During the height of the paroxysm the patient may cry out, so great is her suffering. The paroxysm soon subsides, only to repeat itself at short intervals. The objective symptoms may be quite vague at the onset of the disease, in the acute cases, yet palpation will elicit sufficient symptoms to justify the diagnosis. The lower part of the abdomen is quite sensitive to the touch, particularly when pressure is exerted over the region of the uterus. The recti muscles are stiff and boardlike as well as the other abdominal muscles. Vaginal palpation will reveal an immovable, or only slightly movable, uterus, with exquisite tenderness to the sides of that organ. Masses may or may not be felt in the pelvis. The appendages may not be enlarged to a sufficient degree to be palpable, or the inability to palpate them may arise from the stiffness and unyielding nature of both the abdominal muscles and vagina. Indeed, it may be necessary to administer an anesthetic to clear up the diagnosis. Under anesthesia the abdominal muscles relax and palpation must of necessity be more satisfactory. Pathological masses are then more easily detected, less force is necessary in the examination, hence traumatism of tissues is prevented. The acute process in the oviduct may last for a variable period of time. The virulent types of infection may call for surgical intervention, in from four to ten days following the infection. In the less virulent infections the systemic reaction will be milder and the localized peritonitis less marked, the virulence of the organism may expend itself to a greater or lesser degree and under therapeutic measures subside, and the established inflammation merge into a chronic process, resulting in a chronic salpingitis. The symptoms of this condition may extend over periods of many years. The patients are not very ill, but they are not quite well. There is present more or less a sense of pelvic uneasiness, and inability to stand on the feet for any length of time, backache, constipation, and vaginal discharge are frequent complaints. Impaired digestion, insomnia, and headaches may be mild or quite troublesome in these cases. Dysmenorrhea and prolonged menses may burden these patients painfully and undermine their constitution to no small extent. Indeed in some cases metrorrhagia—which may be the only symptom, may so undermine the patient's health as to force her to seek treatment. Nor is it uncommon in these cases to have interference with the functions of the bladder and rectum. Micturition and defecation are painful, and shooting pains down the thighs and through the pelvis may be noteworthy and distressing symptoms in these pathologic processes. Patients even with the milder grades of chronic salpingitis have days of suffering during each month, if not positively incapacitated. Many of these patients with chronic salpingitis, accompanied by metrorrhagia, undergo repeated currettings, but with little or no benefit. Nothing short of ablation or resection of the tubes seems to be of lasting benefit to them. Quite characteristic in these cases of chronic salpingitis are the repeated outbreaks of localized peritonitis. The patient is taken down with sudden pains in the abdomen, backache, head-

ache, fever, nausea and prostration. The lower part of the abdomen becomes sensitive and palpation of the pelvic contents very painful. These acute exacerbations may confine the patient to bed for a few days, to as many weeks. The exciting cause of these acute outbreaks may be a slight exposure, a menstrual period, fatigue, overwork, coition, and many times no cause can be found. These acute exacerbations may simulate acute abdominal lesions, and in the absence of a familiarity with the patient's previous condition, a differential diagnosis becomes indeed very difficult. In acute exacerbations when the pain is localized to the right of the median line the condition may be mistaken for appendicitis. In appendicitis, however, muscular resistance over the right lower quadrant of the abdomen is greater and a bimanual examination will point to the pelvic pathology. In rare cases, however, both conditions may coexist.

It is usually the acute outbreaks that force these patients to seek enlightenment about their condition, and clamor for relief. When chronic salpingitis is once initiated, the resulting symptoms vary from those of mild to constant suffering. Between these two extremes there are all possible gradations. The majority of cases, however, have symptoms referable to the pelvic region, the nature of which may vary very greatly, even in the same patient. The patient may be quite well one day and sick the next, with vague symptoms—headache, backache, general feeling of depression, nervousness. These symptoms gradually disappear, and in their wake follows another set of an entirely different nature. These may now comprise pelvic pains, profuse menstruation, chills and fever, which may or may not be accompanied by prostration. The general health becomes disturbed, digestion impaired, accompanied by anemia. The pale face, the constant feeling of fatigue, constipation, sleeplessness, lack of appetite, loss of ambition, pelvic distress, aching limbs, leuchorrhea, and backache, make up a train of symptoms in a very large number of the cases of chronic salpingitis.

The treatment of salpingitis resolves itself into palliative and operative. The palliative treatment occupies an important position in the therapeutics of this condition. The natural termination of these lesions is in resolution and cure. The virulence of the infection diminishes, the products of inflammation are carried off by the natural channels, and a restoration *ad integrum* is possible in a very large number of cases. Hence procrastination in operative measures, and judicious persistence in general treatment is to be strongly urged. In the acute cases and the acute exacerbation of the chronic types, the patient is to be put to bed to insure mental and physical repose. Hot applications to the lower part of the abdomen and hot douchings will feel grateful to the patient. The condition of the bowels should be attended to and the diet limited to wholesome and easily digested foods. Anodynes should be administered, in sufficient quantities to relieve pain and insure nerve calmness, while the existing insomnia may call for appropriate hypnotics. Aside from these, the system should not be burdened with medicines, as these inflammatory processes cannot be influenced by drugs. Purging should be avoided, but free catharsis is to be encouraged. Sexual excitement is to be prohibited, absolutely. Stimulants of every kind are to be interdicted. Counter irritation to the abdomen may afford temporary relief from pain, but, of course, it could not influence the lesion in the tube. Tincture of iodine applied to the cervix and vagina can hardly be expected to accomplish much in the relief of pain. It is much better to relieve pain by going directly at it and to administer enough anodyne, either morphine or codeine, to control the suffering. Nothing is to be gained by allowing the patient to suffer for hours and days, yet one should be careful in cases of acute peritonitis not to mask dangerous symptoms by hypodermics of morphine. The opiates used in these very acute cases not alone insures nerve calmness, but act beneficially on the concomitant peritonitis, perhaps by inhibiting the peristaltic action of the intestines. In olden times, before the pathology of peritonitis was known, opium was the sheet-anchor in the treatment of this lesion. The clinical observations of those days no doubt showed the favorable results obtained with this drug. Having placed the patient in bed and having brought about a state of mental and physical rest, relieved suffering, properly attended to diet and bowels, and having procured sleep and comfort for the patient, we may now wait for developments. Daily examination of the patient will be necessary to be familiar with the progress of the affection and to detect pathological changes as they arise from time to time during the process of the disease.

Local treatment may or may not be necessary in these cases. If the salpingitis is of gonorrheal origin, and if active inflammatory processes of the external genitalia are still in evidence, these local lesions should, of course, receive appropriate treatment. First of all, strict cleanliness is necessary. This is accomplished by frequent douchings of hot water, medicated or not. I prefer Pot. permanganate solution for the purpose. The solution is made of varying strength, depending on the stage of the disease. In the acute stages a milder solution, while in the chronic stage a stronger solution is used. These douchings and irrigations are carried out in a systematic way. If a urethritis is present the lesion receives treatment at the same time. The patient is placed on a douche pan and the vulva thoroughly exposed. If the urethra is infected, the irrigation is begun there. If the inflammation of the part is at its height, the urethra is cocainized first. A little adrenalin chloride added to the cocaine will enhance the anesthetic effect of the drug. Having cleansed the urethra, the vulva and vagina are next douched—care being exercised not to inflict injury to the congested mucous membrane of these parts. Even if the uterine cavity harbors an active infection, no attempt should be made to treat the cavity topically, except under one condition, and that is when the uterus contains retained secundines. Under such condition the uterine cavity should of course be curetted, with tact and gentleness, to avoid unnecessary traumatism of an already much inflamed organ. If the uterus harbors foreign tissue material, the cervix will be partially open and very little divulsion will be necessary for the introduction of a small sized curette. Even with a small instrument, these uterine cavities will admit a thorough cleansing, and a dangerous wide dilation of the cervix in these cases is unnecessary. The existent vulvovaginal abscesses should be opened and treated judiciously. If the infection is of pyogenic origin the points of inoculation when discovered should be dealt with in an appropriate surgical manner. Antiseptic applications and irrigations, with liberation of pus and absolute cleanliness, are the keynote in the treatment of the various lesions of the urethra, vulva, vagina, and cervix.

If under palliative treatment the infection does not have a tendency to subside, and if symptoms of sepsis arise, operative intervention is called for. In the presence of an active inflammatory reaction in the pelvic organs, with concomitant peritonitis, and

in the face of a virulent infection, operative intervention is a matter of serious consideration. A factor is introduced in the acute cases that is not encountered in the chronic types of salpingitis. This factor is that arising during the operative act—the possible contamination of the not yet invaded tissues with virulent germs, and the possibility of inviting a fatal sepsis. The safest course to pursue is to incise by way of the vagina and drain until the symptoms of sepsis are under control and the virulence of the infection diminished. When this state has been reached, radical operations may be undertaken with comparative impunity, and with considerable hope of obtaining a complete cure. So alarming is the mortality of radical operation during the acute exacerbations, that it is a questionable procedure. It is but seldom the case that the symptoms of sepsis cannot be kept in abeyance by incision and drainage. An incision of Douglas's cul-de-sac and evacuation of pus will usually bring about a cessation of symptoms with improvement of the patient's condition. In performing posterior section for pus, all inflammatory masses that are to be felt in the pelvis should be broken up, so as to liberate pent up purulent materials. Particularly, should the tubes be sought for and incised, if practicable, or punctured if they cannot be brought within reach for incision. Pelvic abscesses should be drained with gauze packings or drainage tubes. Abscesses situated in the broad ligaments may call for thorough drainage, and appropriate external abdominal incisions may be necessary for that purpose. True pelvic abscesses, however, particularly those arising during puerperal sepsis, may also be so situated as to call for external incision for the liberation of their contents. As a rule, however, true pelvic abscesses can be evacuated by means of a posterior vaginal incision. This vaginal incision should be ample, as these incisions have a tendency to heal up rapidly, and in doing so may defeat the object in view, of providing an outlet for the pus. After the evacuation of the pus the patient's condition will be such as to call for most careful therapeutic efforts on the part of her physician. Good nursing, careful dieting, supportive and hygienic measures are called for in the treatment of these septic cases. Medicinal measures as a rule are of little avail, yet what little benefit is to be derived from drugs that tend to support the constitution is to be strongly recommended. Alcoholic stimulants, in my opinion, should be avoided. Alcohol may be an excellent food material, yet it will be more advisable to nourish the patient with foods of a more natural origin than alcohol. If the collections of pus in the pelvis are not evacuated surgically, nature may accomplish this in four different ways. The pus may become encysted and remain so for an indefinite period of time. It may be discharged through the uterus. The abscess cavity may perforate into the intestine, bladder, rectum, or into the peritoneal cavity, or the pus may become absorbed by the natural channels.

With the virulence of the germs causing the infection diminished, the inflammatory processes in the uterine adnexa subsides. The peritonitis stops and the patient's condition may progress to cure, or, what is more frequently the case, they may remain chronic invalids if left to themselves. It is in these cases where treatment by operation brings about cures that nature has failed to accomplish unaided. The surgical treatment of these cases has, fortunately, become intimately blended with what at the present day has become known as "conservative gynecological operations." The routine removal of the adnexa *en masse* has given way to the removal of one or more parts of these organs that have become hopelessly crippled by disease. This conservatism has of course introduced an important problem, that of knowing what to leave and what to remove of the damaged uterine adnexa. It is the problem of bold or timid conservatism. The boldly conservative will satisfy himself with simply liberating the tubes, ovaries, and uterus from their beds of adhesion, liberate intestinal coils and omentum from their false positions, and remove such organs or parts of them as he finds hopelessly diseased; while the timidly conservative will only leave behind organs that appear to be normal beyond a doubt. Both of these workers may give abundant proof to maintain their contentions, for in this field of surgery there is abundant room for both positions. At times it becomes most difficult, during an operation, to judge correctly which road to take. This matter of conservatism, however, becomes simplified when the surgeon has before him the wishes and desires of his patient, as regards sacrifice of her organs, or the willingness to risk another operation, in the event that the bold conservatism has erred, and left behind parts or organs whose extirpation would have served better. If this matter is placed before patients of child-bearing periods, their decision will usually assist the surgeon in deciding what will be best for this particular patient. Each case is a law unto itself. The social condition of the patient is a matter of considerable importance. The patient in easy circumstances will take more readily the risk of a second operation, should this be necessary, than her sister in less fortunate circumstances. Then again, the desire for offspring is by no means a criterion in this matter. She who has children may be willing to sacrifice both adnexa in the event that the slightest risk should exist for a second operation, while the one without issue may beg for the retention of her tubes and ovaries at almost all hazards. Conservative operations on the uterine adnexa, aside from the question of reproduction, take into consideration two matters of vital importance to the patient's well-being. One is the menstrual function, and the other the internal secretions of the ovaries and the purpose they serve in the female economy. Menstruation is so intimately connected with her nature that its sudden cessation brings most unpleasant sequelæ. Artificial menopause has symptoms in its wake that are at times exceedingly distressing to the patient and frequently most profoundly react on her physical and mental state. If all the disagreeable, nervous phenomena can be removed by conservatism on the ovarian tissue during operation, the procedure calls for ready adoption by the physician, for it is the glory of his therapeutics not alone to remove diseased structures from the body, but to leave the human economy in as natural a state as possible. A further reason why removal *en masse* of the uterine adnexa is to be deprecated is the fact that it is foreign to modern surgery to remove tissues or organs that are not pathological, and that may become normal at a future time. While nothing definite is as yet known about the chemistry of the mysterious ovarian secretions, clinical facts point strongly to their existence and their usefulness in the human organism. Chemistry shows that the so-named "Spermin" is found in the thymus and thyroid glands, as well as the ovaries, spleen, and testes. Physiological chemistry shows further that this substance is an active oxidizing agent and may have some such a function in the animal economy to keep the physiological balance true. It is in the interest of the preservation of the three functions of the ovary; namely, ovulation, menstruation, and secretion, that conservative surgery on these organs is so important. Even in patients that have passed the

climacteric period, where two of the functions of the ovary, ovulation and menstruation, are negligible matters, the third function may still be of importance, for it has not been shown that internal secretion of the ovary ceases with the cessation of the other functions. As regards conservatism on the tubes and uterus, it needs only to be mentioned that these organs are occupied with the performance of but two functions: menstruation and pregnancy. Therefore, in a patient past the procreative period, conservatism on these organs does not hold so important a place. However, even in patients in this age laparotomized for diseased adnexa, the removal of the uterus, unless absolutely necessary, should not be undertaken, without due regard to the condition of the patient at the time of the operation, as hysterectomy is accompanied by more shock than the more simple operation of salpingectomy. If the uterus is diseased it should of course be removed, because infected uteri are as much of a menace to life and health as diseased adnexa, and in sparing the organ one might not spare the patient.

Conservatism in operations on the uterine adnexa embraces the liberation of these organs from false positions and adhesions; the removal of hopelessly diseased parts; the evacuation of purulent material and cleansing, and the proper and judicious drainage that may be instituted with the hope of an ultimate recovery of the infected tissues. Nothing but the hopelessly diseased parts of these organs should be removed, and with a uterus not too much damaged by disease, even the boldest conservatism on the appendages is permissible. Enough cases are on record showing the excellent, immediate and remote results of such bold conservative operations to justify the most sanguine expectations. In chronic salpingitis, even purulent collections in the tube may be ignored. Such tubes may regain their anatomic and physiologic integrity after the evacuation of the pus, and need not be removed *in toto*. Experience has demonstrated that these purulent collections are practically sterile. By liberating them from adhesions, evacuating their pus contents and cleansing them, they may so far recover themselves as to functionate again. Cases are on record where pregnancy followed the removal of a hopelessly diseased tube on one side and the cleansing and resection of the opposite one. Surely in these cases the resected tubes have given enough evidence of their ability to again perform their function of carrying the ovum to the uterus; in fact, the highest kind of evidence of return of function. Parts of the oviduct may be removed, new openings established by stitching the mucous membrane to the peritoneum, tortuosities remedied by liberating adhesions or exsecting nodules from the tubes. Tubes with many of these nodules, however, had better be extirpated, as these lesions frequently prove on examination to be of tubercular infection. If the whole tube is to be removed, the organ can be liberated from its mesosalpinx and the uterine end excised from the uterus by a few well-directed incisions. The rent in the uterus is then closed and the mesosalpinx approximated with a running suture of fine catgut. The integrity of the broad ligament need not be interfered with, nor shortened, as is the case when the adnexa are tied off *en masse*. If both tubes and ovaries are so hopelessly damaged by disease that their total ablation is essential, it becomes a question of some importance whether the uterus should be removed or not. Hysterectomy is an additional operative risk and should not be incurred unnecessarily. If the uterus is enlarged, congested, and particularly if there is reason to believe that it is infected, it should be removed, because such an organ will hinder the recovery of the patient. An infected uterus left behind after salpingo-oophorectomy is frequently the cause of continued ill-health, and necessitates secondary operations for its removal. It is at times quite difficult, during the operation, to make the proper discrimination as to which organ to leave, or which to sacrifice. Hysterectomy is also called for when the uterus harbors neoplasms.

While conservative operative endeavors should be the guiding spirit in chronic affections of the uterine adnexa, in the acute cases total ablation will more often be called for. Resection of tubes and ovaries in subacute or acute cases enhances the risks of peritoneal contamination, and invites sepsis. In these cases panhysterectomy with judicious provision for drainage by the vagina will crown the endeavor with success in many cases that otherwise would be lost, Many uteri in the presence of adnexal disease have long ago regained their normal state, particularly if the uterine ends of the tubes have become obliterated and no infection reaches the endometrium from the oviduct. Therefore, the retention of this organ, even though ovulation and menstruation have stopped, is indifferent to the patient. If this is true, why burden the chances of a laparotomized patient with the additional risk of a hysterectomy, a risk that exists in the removal of even a normal organ? Again, even uteri that do harbor infection by virtue of the endometrium being bathed with infective material coming from patent infected oviducts, may in time regain their normal condition when the tubes are ablated, and the source of infection removed.

In considering the technique of salpingo-oophorectomy or salpingo-oophorotomy it is not alone necessary to have recourse to a thorough familiarity with the anatomy of the pelvis and its contents, but that the sense of sight and touch of the operator should be harmoniously exercised. The axiom to see what one does and to do what one sees, applies in the surgery of no region of the body more emphatically than in operations on the uterine adnexa. In diseased states of the contents of the female pelvis, the distortion of organs and tissues may be startling and bewildering. Organs whose normal situation is that to the right of the median line, may be found on the left side, or *vice versa*. Coils of intestines that normally are loose in the pelvis may now be found bound down by well organized bands of adhesion. The rectum and uterus may intimately blend and the sigmoid flexure of the colon may roof the fundus and bladder. Ureters may be drawn out of their normal position, and blood vessels may take atypical courses. Such a complicated state necessarily calls for acute identifying powers on the part of the operator, and hence sight and touch are called into activity. The first consideration in the technique of the operation is to obtain a good view of the pelvis. In abdominal operations this calls for a free median incision. With the patient in Trendelenburg position and with the retracted abdominal wall of a free median incision a good view of the pelvis is commanded, and the most important landmark located. This landmark is the body of the uterus. If coils of intestines, sigmoid flexure, rectum and omentum hide this landmark, these structures should first be separated and dealt with *secundem artem*. In separating adherent coils of intestines, the lines of cleavage should be sought for in liberating these adherent structures. Coils of intestines damaged in the process of their enucleation from adhesions should be repaired at once, with properly placed sutures. Immediate attention to these damages will save time and insure certainty in their repair. Once these loops of intestines slip the fingers their repair may be forgotten and difficulty may be encountered

in their subsequent identification. Adherent omental tags should be liberated and the bleeding points of severed parts secured and tied. These bleeding points, if ignored, are not alone of danger to the patient, but hinder the operation by inundating the field with blood and interfering with vision. The intestines liberated from their false position, and damages properly repaired, are further protected from injury and possible contamination by properly placed abdominal pads. The intestine out of the way and tucked in with gauze, the field of operation is now in full view and control. If infectious material should escape during the course of the ablation of the adnexa the gauze pads will absorb it, and soiling of the peritoneum be more or less prevented. The body of the uterus having been properly located, and the fundus liberated from adhesions the organ may be grasped with a volsella forceps for security and control. The identification of the adnexa is now less difficult, and with the uterus under control their liberation from adhesions more easily accomplished. The freed tubes and ovaries are inspected with the view of practicing conservatism on them or condemning them to resection. The tubes may be probed to discover their patency or occlusion; they may be cleansed and washed, pus may be evacuated, or they may be resected in part or *in toto*. The ovaries may be dealt with in a similar manner. Adhesions may be severed, pus evacuated, cysts punctured and resection practiced in part and in whole.

After extensive enucleation, considerable oozing and bleeding may be encountered. These points of hemorrhage should be diligently sought for and controlled, if necessary with a needle and ligature. Oozing that cannot be controlled by pressure and hot pads should be covered over with peritoneum, if possible. Sometimes tags of adhesions will bleed quite readily and may be controlled by compression with clamps. Even extensive raw surfaces may be covered with peritoneum by exercising patience and some ingenuity. If much soiling of peritoneum has occurred and if there is reason to fear virulence of the infection, drainage should be provided for through the vagina, or the operator may only deem it necessary to irrigate the peritoneal cavity. Before closing the abdomen the pelvis should be dried and once more thoroughly inspected, not to overlook bleeding points and pathological masses.

An article on the treatment of inflammatory lesions of the uterine adnexa would hardly be complete without reference being made to the conservative surgery that may be practiced on the tubes and ovaries, through the anterior vaginal incision, so ably and persistently advocated by Dr. J. Riddle Goff of New York. In a very large number of cases of adnexal diseases the anterior vaginal incision will admit an incredible degree of access to these lesions. Through such an incision oviducts may be liberated from adhesions, resected or exsected, with considerable ease. The same may be said of the ovaries. They may be removed through these incisions or conservatism practiced on them at will. Not alone the uterine adnexa but frequently the appendix can be demonstrated and dealt with surgically through this incision. This considerable accessibility to the contents of the pelvis is obtained by making two incisions, one at right angle to the other, like the lines of a capital letter T. A horizontal transverse incision is first made in the anterior wall of the vagina, along the cervicovaginal junction. At the center of this incision a vertical line of incision joins it, which is carried along the anterior wall of the vagina in the median line, if necessary, up to the lower border of the pubic arch. Before making the vertical incision, the bladder is separated from the vaginal wall, cervix and uterus. By thoroughly separating the bladder from the vagina there will be little danger of wounding that organ. Nevertheless, in making the vertical incision in this operation, care should be exercised not to injure the bladder wall. The peritoneal cavity having been entered, the fundus of the uterus is drawn forward and its posterior surface brought into view, and the liberation of the adnexa accomplished with considerable ease. If they can be freed sufficiently the ovary and tubes may now be delivered into the vagina and dealt with in accordance with the operator's wishes. When the operation on the delivered adnexa is finished, the organs are returned into the pelvis and their fellow structures similarly dealt with. While a good per cent. of cases of adnexal lesions can be dealt with by this incision, a very large number of cases will demand abdominal section for their cure.

SOME OPHTHALMIC SUGGESTIONS.*

By RICHARD KALISH, A.M., M.D.,
NEW YORK.
OPHTHALMIC SURGEON TO THE CITY HOSPITAL, CONSULTING OPHTHALMIC SURGEON TO THE ST. JOHN'S LONG ISLAND CITY, AND J. HOOD WRIGHT MEMORIAL HOSPITALS.

The scope of this paper is indicated by its title, the suggestions being the outcome of observations made and experiences gained in the practical treatment of diseases of the eye.

The sensational exploitation by the monthly magazines and the daily newspapers of their so-called medical discoveries, which were old and discarded ideas when the science of medicine was young, is responsible in many instances for misconceptions relative to medical matters, involuntarily assimilated both by patient and physician.

These self-styled scientific articles are published again and again, and their repeated reiteration makes so deep an impression on the minds of readers that finally an indiscriminate acceptance is brought about much in the same way as a lie oft repeated will pass current for the truth. This is singularly so in medicine, since denial is never made. No matter how incongruous or how inaccurate—from a medical standpoint—may be the argument in a non-professional publication, physicians hesitate even to notice these falsities because of the usual and natural repugnance against the discussion of medical subjects in the lay press.

Thus erroneous assertions are accepted as demonstrated facts, not only by that class of superficial readers in whose shallow and imaginative minds fact and fancy play a loose hide and seek, but also by cautious and discriminating readers who are deceived by the plausibility and apparent plainness of the statements. It goes almost without saying that these accounts often contain a germ of truth, some little information, and they thus exemplify the rule that in medicine as in the everyday walks of life, a little knowledge is a dangerous thing. The popular definition and explanation of vision are somewhat involved and address themselves to the reader's understanding or rather to his misunderstanding as part of that mysticism which has ever played an important rôle in medicine from the early dawn of civilization, when the priesthood dominated and directed this science, down to the present day when so many bacteriologists play pranks with facts and microorganisms. It has thus come to pass that every statement in regard to the eye itself or to the function of sight, no matter how absurd it may be, is accepted

* Read before the Northwestern Medical and Surgical Society, January 18, 1905.

with a ready credence that is as ludicrous as it is astonishing.

The eye occupies so exposed a position that changes in its appearance may be observed easily, which fact has been advantageously used by the self-prescribing laity, who, fortified by an assumed semblance of knowledge, do not hesitate to claim the ability to differentiate diseases of the eye and to direct treatment for their cure. In doing so, advice is often given that would be farcical were it not utterly wrong and in some cases distinctly criminal.

The senseless outcry against the wearing of glasses by the young is a favorite theme. These misguided critics express wonder that "so many children are wearing glasses, for in their time it was not so, only old people wore spectacles," and from inner consciousness, that most inaccurate of mentors, they evolve reply: "It must be for style," they say, or "the oculist felt that he had to order something," or "it was a fad," etc. It is just these *ex parte* statements, originating in dense ignorance, but accepted as truths by those equally ignorant, that so often interfere with the recognition of visual defects. The common and more than common remark, "if you put on glasses, you will always have to wear them, so do not wear them at all," is as trite as it is misleading, since it is responsible for great physical suffering, its observance being the cause of many a failure in life's work, and the wrecking of what under other circumstances would have been a successful career. It one be halt, he requires crutches to help him over rough places and for comfort and safety will always require a crutch; so if vision be defective, glasses to overcome the faulty condition are urgently and continuously required. Glasses are for imperfect sight just what crutches are for limping gait, and both are demanded just as long as the blemish remains. To lay down a law that the young should never wear glasses is a false dogma that cannot be too emphatically censured, for the records of every oculist exhibit scores of young pupils, dismissed by teacher and parent as hopelessly stupid, who, through the medium of properly adjusted glasses, have emerged from the gloomy midnight of mental torpor into the bright noonday of intellectual activity.

Whence has arisen the heresy that squint in children should go untreated, "as they will outgrow it," is hard to discover. And yet this fallacy has become almost an orthodox belief to physician, parent, nurse, and fond grandmother. No advice could be more mischievous or fraught with greater peril to the deviating eye. A squinting eye is a disabled eye, which soon ceases to be used, and if this disuse be allowed to continue, it eventuates in a permanently undeveloped eye valueless as a visual organ. It is the moral duty of the physician to prevent loss of function of any organ of the human body, and neglect to preserve the action of such organ is reprehensible. It is unfortunate that the popular and generally accepted belief should be that treatment of squint in children is undertaken solely for cosmetic effect, but no opinion could be more erroneous. To obviate loss of function is the impelling and controlling cause, and not to improve the good looks of the child. This false idea prevails probably because in the adult, cosmetic benefit is, in the majority of cases, the object aimed at, but distinction must be made between the result secured in childhood and that obtained in maturer years.

It is generally conceded that the distinctive feature of squint in children is a defect in image fusion. Light reflex and fixation reflex are both present from early infancy, and attempts at binocular fusion come on early in life, probably by the sixth or eighth month.

Experiments have shown that when a prism of moderate strength is held before one eye of a child ten to sixteen months of age, an attempt is made, at once, to get rid of the diplopia by moving the head or by closing one eye, thus showing that the faculty of binocular fusion is fully developed at that age. In squint, defect in image fusion is accompanied by a recognizable amblyopia in the deviating eye as well as some muscular imbalance; but this latter is now regarded as a result rather than as an element in the causation of strabismus. Squint in the majority of cases comes on before the third year and treatment should be inaugurated just as soon as the condition is observed. It is astonishing how rapidly under proper treatment, a squinting eye of feeble receptive power will develop into a useful member. Objective methods in examination have become so perfected that oculists are now able to determine the visual fault accurately and to institute treatment adequate to overcome the defect. No child except an infant in arms is too young for non-operative treatment, and this should be commenced at the earliest possible period and fully and insistently carried out. This treatment consists first, in correction of the refractive error; second, in compelling the use of the squinting eye, and lastly, in regular exercise of the fusion faculty. If this treatment be regularly and rigorously used, from 70 to 80 per cent. of the cases of squint under seven years of age will be cured.

By far more damage to eyesight is done by the self-fitting of glasses than by any other so-called help. The term self-fitted is used advisedly, for at department stores, opticians' shops, and refractionists' parlors, the applicant fits his own eyes. The term refractionist is so generally and so loosely employed that it requires definition. The last edition of Dunglinson's Dictionary is the only book in which the word was found. A refractionist is "one who discovers and endeavors to correct errors of refraction in the eye." Observation compels me to modify this to, "One who endeavors to discover errors of refraction in the eye in order to sell glasses therefor." A single visit to any of the establishments where glasses are "fitted without charge," will demonstrate that glasses are self-fitted and without the help of the man who charges for the glasses. The victims, and there is usually a row of them, stand at a long counter, or occasionally one may sit down at a small table, and glass after glass is tried on until one is found that fits. This is then paid for—which is the chief consideration—and the patient departs. Now where is any science, skill, or experience manifest? What has seemed best has been accepted as correct without further examination or verification. Not 20 per cent. of such eyes are accurately or adequately corrected as to the refraction error, and sooner or later it is discovered that serious damage has been done. One broad rule cannot be too strongly urged, and this is that glasses should never be ordered without an ophthalmoscopic examination of the eye ground having been made prior to the prescribing of the glasses. To this rule there is no exception. Failure to make such an examination ranks with the omission of a physical examination when symptoms of pulmonary trouble are noticed. What physician would treat a sick man for pneumonia, because he has had a chill and has a hacking cough, and yet because a patient says that he cannot see as well now as in the past, he is told to go and get a pair of glasses. This statement is made to emphasize the fact that there is a widespread belief that anyone can fit glasses. This idea on the part of the laity, and of many in the profession as well, arises, in my opinion, from two causes—in the first place from the description in the lay press of

methods of self-fitting in glasses in the form of reading advertisements which appear in the guise of scientific articles; and in the second from the indifferent manner in which this subject is treated at the junior medical schools together with a failure there to lay especial stress upon the necessity for thorough and painstaking examination of the eyeball and its appendages. This is said with great reluctance, but is due to the writer's experience with picked graduates of the large medical schools, who have been house officers in the hospitals to which he holds visiting relations.* It must also be confessed that some oculists have erred in this particular. Occasionally it has been my experience to be informed by patients that although their eyesight had been examined previously both by prominent oculists and by opticians, the methods had been the same, at no time had an ophthalmoscopic examination been made.

The misfortune as regards the so-called refractionist is that he does not know; therefore he cannot comprehend his limitations. A six weeks' course at some spectacle maker's warehouse or, as is more often the case, the purchase of a cheap supply of glasses for fitting eyes is his sole qualification. Prodigious indeed must be the brain that can acquaint itself with every ocular disturbance and disease in so brief a period, and reckless in the extreme a man must be to consent to differentiate conditions of the eye with so meager and so incomplete a preparation. Mistakes are, therefore, sure to happen, and a very brief outline of a few cases observed in my private practice will serve in illustration of several types in which improper glasses were given by so-called refractionists.

A young man 25 years old, clerk, writing all day, complained of pain in the eyes. A weak minus cylinder given by a refractionist relieved the pain for a week or so, after which the pain returned. My examination showed distant sight to be 20/20 or normal. Ability to read was good, a low degree of hyperopic astigmatism was found to be present, and trial of a weak convex cylinder brought out the remark: "It doesn't seem as if I had on any glasses, just using my own eyes." He has used this same glass for a number of years and the pain has not returned. Now if that optician had had any knowledge whatever of refraction work, he would have known that with sight for distant objects equal to normal, there could be no manifest near-sighted astigmatism; but as the complaint included a statement that small objects had to be held nearer to the eye than formerly, and, in reading, the book must also be near to the eyes, the optician jumped to the conclusion that this was a case of myopia, and sold the applicant a weak minus cylinder because he said that it fitted his eyes. No attempt was made to verify his guess by use of ophthalmoscope, ophthalmometer, or skiascope, nothing but the acceptance of a glass held before the eye for a brief moment. Mistakes of this character are of so frequent occurrence that scarcely a week passes but I have one or more experiences identical with the above.

A not unusual blunder on the part of the self-fitting spectacle seller is failure to recognize muscular insufficiency coexisting with error of refraction. In this condition, the near or far-sighted defect is corrected, usually over-corrected, and the undetectable muscular imbalance goes on to the lasting detriment of the innocent sufferer. The involuntary strain required to clear the blurred image produces headache and a mild brain fag evidenced by a mental apathy, which is misinterpreted to be laziness or stupidity.

A different type of cases and one that owes disaster to sight to self-fitting, is chronic primary or simple glaucoma. This disease, as is well known, is often insidious in its onset, and advances by very slow degrees. Under proper treatment when discovered in its incipiency, its progress may be retarded for years and occasionally to the end. The symptom most frequently noticed—in my experience—is distinctively subjective, a little dimness of sight with reduction of reading power, which is always ascribed to advancing years. The danger arising from failure to distinguish simple glaucoma from presbyopia is strikingly shown in a comparison of the histories of two groups of cases taken from my records. In both groups the symptoms were purely subjective, and for this reason a comparison is instituted, as it would be manifestly unfair to place in juxtaposition cases in which symptoms were not identical. The first group consists of three cases with similar histories. Inability to read clearly and some reduction of sight for objects at a distance. Fitted to glasses by opticians, in three months stronger glasses were required, another increase in two months, again increased in two months. Then the usual objective symptoms occurred followed by regular treatment and iridectomy to relieve the pain, recognition of light being the only visual function retained. The second group consists of nine cases who came for glasses "to read and write with, as they could not see to do these things as well as when they were younger." In these cases, glasses were prescribed for near work only. The examination showed presbyopia, no symptoms of any other trouble being discoverable. The further history of these cases is: In one case sight for distant objects was reduced from 20/20 in December to 20/200 in the following March. Full contraction of the pupil under the influence of eserine brought the sight up to 20/50 in two hours, and in three days, the sight under eserine instillations returned to normal or 20/20. In four cases distant vision of 20/200 returned to normal or 20/20 after five days' use of eserine. In three cases with a distant vision of 20/70, normal sight for distant objects was restored in four days under the use of eserine, and in one case a distant vision of 20/50 returned to normal after 24 hours' use of eserine. These patients still retain their restored sight.

In view of these results, it certainly is a just conclusion that even if the first group had not been permanently benefited, early treatment would certainly have delayed for a time the disastrous result. At the present time I have under my care a number of cases of chronic primary glaucoma in which no material advance has been made for periods ranging from four to six years, and my records show that several cases have been under observation and treatment for ten years without appreciable damage to sight occurring, good vision being retained to the end of life.

It is evident that whoever fitted the eyes of the three patients in the first group must have been ignorant of the first principles of refraction work, for when they appeared at the end of the three months and much stronger glasses were required, but one of two conclusions could be tenable. Either the fitter had made a mistake and given too weak a glass, or something had happened to the eye. When the third visit was made two months later, the optician

*In the discussion that followed the reading of this paper, it was said that lecturers at the colleges recommended ophthalmoscopic examinations in cases of refractive errors. Further investigation shows that while this advice is given, it is honored in the breach. Recent graduates assure me that during practical instruction in the fitting of glasses, the opthalmoscope is hardly ever used. So rarely indeed is this the case that until their attention was called thereto by my questions they had forgotten that this instrument had any use except in obscure and doubtful diseases of the eye and brain.

should have known that disease existed, declined to give the stronger glass and insisted that an oculist be consulted. He should have known that presbyopia pure and simple does not advance with such lightning like rapidity as to call for an increase in the strength of the glasses from 1½ D to 6 D in the short space of five months. That certainly is crowding "old sight" a little hard. Instead of advising the applicants properly, glasses were supplied—at the usual price—and irremediable blindness resulted.

The duties of oculist and optician cannot be combined in the one person, for the function of each is distinct and separate. The oculist's work is to *examine* the eyes and when the nature of the deviation from health has been determined, measures to overcome the defect are to be ordered. An optician's business is to sell glasses, which is of necessity commercial. In this age of frenzied finance and get-rich-quick schemes, might not this spirit prove too strong and the business part of the work impel him to sell glasses where the services and knowledge of a specialist were required rather than the use of glasses? It is immaterial to an oculist whether he prescribes glasses or not; but is distinctively material to an optician to sell glasses, his means of livelihood often depending largely upon the extent of these sales, and in his zeal to increase his business, the temptation to accept any improvement of sight by glasses might prove irresistible. The relation of the optician to the oculist is identical with that existing between the pharmacist and the physician; the former in each case preparing according to instructions the prescriptions of those skilled in the treatment of physical imperfections.

In conclusion, the opinions expressed are offered as suggestions to medical men and are not to be taken in any sense as a criticism of the practice of medicine. They are presented as a reminder only, in truth as an additional "lest we forget."

Relative to the self-fitting of glasses, the opinions expressed are offered as an emphatic protest against the methods employed by so-called refractionists and opticians and these opinions rest upon the strongest foundation, namely, proven fact. Now facts are stubborn, unanswerable things, and these facts are confirmed a hundred, yes, more is the pity, thousands of times, by the experiences and records of oculists in active practice.

36 West Forty-seventh Street.

THE HEART AND CIRCULATION IN THE PROGNOSIS AND MANAGEMENT OF PULMONARY TUBERCULOSIS.*

By SILVIO VON RUCK, M.D.,
ASHEVILLE, N. C.
ASSOCIATE MEDICAL DIRECTOR OF THE WINYAH SANITARIUM.

The relation of the heart and circulation to the course of chronic pulmonary tuberculosis is a factor both in the prognosis and management of such cases which is not generally accorded the attention and study which its importance demands. Even in the earlier stages of the disease the obstruction to the lesser circulation not infrequently exerts influences upon the heart of far-reaching significance, and quite rightly in this connection many authorities look upon a rapid pulse in an early stage as a very unfavorable prognostic indication. Upon this symptom, with or without attacks of tachycardia, Brehmer based his theory of a relatively small heart as standing in etiologic relation to the occurrence of phthisis. In this he was no doubt influenced by the findings of Laennec,[1] who showed this relation, and also by Louis,[2] who claimed to have found the heart relatively small in 109 of 112 cases. Brehmer was a life-long advocate of this theory, having first proposed it in his Doctor's Dissertation in 1853, and having further elaborated it in his subsequent work on chronic consumption[3] and its etiology.[4]

This theory, which is now practically abandoned, was also supported by Rokitkansky,[5] who, like Beneke,[6] considered the small heart a congenital hypoplasia and, despite much opposition, it remained dominant until about a decade ago, when Crook[7] still recognized it and stated that in 77 per cent. of autopsies of consumptives the heart was smaller than normal. Since that time the view that the apparent smallness of the heart as observed after death from phthisis is rather an effect than a cause of the disease has gained constant recognition. Laennec[1] had already suggested this in his time. Potain,[8] who often found a small heart attributes it to general malnutrition. Reuter,[9] in his study of the subject, in 1884 showed that the relation was by no means so common as was generally believed. He found from autopsies at the pathologic institute in Munich, small hearts in men in only 29 per cent. and in women in 56 per cent., while the hearts were larger than normal in 40.2 per cent. of the men and in 20 per cent. of the women. Lebert[10] called attention to the actual occurrence of hypertrophy in 1874, and among others, Herard, Cornil and Hanot[11] in 1888 again remarked the clinical phenomena of a weak and dilated or an hypertrophied right ventricle, ascribing these conditions to the increased resistance in the pulmonary circulation by reason of structural change in the lungs, Portal[12] having shown the presence of enlargement and dilatation of the right ventricle a century before. West[13] also refers the small heart found post-mortem to the general emaciation, and recognizes the occurrence of hypertrophy of the right ventricle in the course of phthisis. On the whole, we find that at an earlier period in the last century most authors were inclined to look upon a small heart as a cause of phthisis. Others saw in its presence after death only a result of general wasting and muscular atrophy, while in the further course of the study enlargement, especially of the right ventricle, with or without evident dilatation, attracted attention, and the relation of the latter to obstruction in the pulmonary circulation became more and more recognized.

Clinically the rapid and weak pulse and attacks of tachycardia were frequently considered diagnostic, and many authors have likewise recognized their unfavorable prognostic import. Sir James Clark,[14] for instance, speaks of a rapid pulse as strongly corroborating the suspicion of the existence of pulmonary tuberculosis, without, however, attempting an elucidation of the cause, which even at the present time is still looked upon as due to a naturally small heart. The autopsy findings of some of the authors referred to, and especially those of Reuter,[9] offer to Bohland[15] the most rational explanation for the occurrence of tachycardia in the course of phthisis. Other explanations for this symptom have been sought in attending anemia, digestive disturbances, and fever. Burckhardt[16] attaches no particular significance to it, and thinks that little can be learned from the observation of the pulse in the early stage. According to him, the frequency of the pulse corresponds to the advances of the disease, becoming increased in the second and permanently rapid in the last stage. Herard, Cornil, and Hanot[17] mention the occurrence of tachycardia as entirely independent of

*Read before the Tri-State Medical Association of the Carolinas and Virginia, held at Greensboro, N. C., February 28 and March 1, 1905.

fever, and they, as many others, believe in a relation of reflex irritation of the pneumogastric. Cornet[18] admits among other causes neuritis of the pneumogastric to be an occasional one, ascribing, however, the greatest influence to toxins of the tubercle bacillus and of other pathogenic bacteria which weaken the heart and cause vasomotor excitability, thus lowering the blood pressure, which Marfan[19] found below normal in 97 of 100 cases of phthisis. Faisan[20] also accepts the toxin theory, though in some cases he recognizes as a cause compression of the vagus by enlarged bronchial glands. The same views are held by A. Fraenkel.[21]

The toxin theory, which is always convenient for accounting for phenomena which we cannot readily explain, is made the most of by Patton,[22] according to whom there exists in phthisis a veritable toxemia of the heart muscle, which accounts not only for a rapid and weak pulse, faintness, dizziness, dyspnea, gastric disturbances, imperceptible heart impulse, possibly signs of dilatation and weak first heart sound, but also for a relatively intensified second sound. In the latter effect the toxins, so much blamed for weakening the heart, appear to have a redeeming feature, in that they strengthen it as well.

While thus opinions are still at variance as to the cause, there is quite a uniformity of conviction as to the prognostic significance of tachycardia, especially when it occurs in an advanced stage of the disease. Rühle[23] and also Heitler[24] have dwelt upon it at length, and recent authors recur to it whenever writing of the symptomatology of phthisis. Loomis,[25] Cornet,[26] Campbell,[27] and others consider a rapid heart action of unfavorable import in the early stage also, and Campbell attaches the greatest importance to the observation of the pulse. Likewise does Sterling,[28] who showed the comparatively less favorable course in patients with a rapid pulse although still in an early stage. Schütz,[29] who studied the subject at a sanitarium for consumptives, found even evidence of slight dilatation in an early stage of the disease, as shown by accurate physical examination as well as by clinical symptoms. Bohland,[15] however, holds that simple tachycardia may exist for a long time without detrimental results, and that it often remains a sequela after the patient has recovered. Only its persistent presence or a high degree of tachyardia is in his opinion of serious consequence.

Among clinicians there is a general accord in viewing a persistently rapid pulse or attacks of palpitation with considerable misgiving, regardless of the supposed causes, which doubtless can be various. In clinical study I have not been able by physical examination to demonstrate a strikingly small heart during the life of the patient. Neither can I accept the theory of reflex irritation of the pneumogastric which, if present, should rather cause a slow than a rapid heart action, while the toxin theory I consider entirely speculative and as having no support whatever. I am the more inclined to disregard it, since tachycardia is frequently present without fever or other symptoms which one would expect from such intoxication, and is absent in many other instances in which fever and other symptoms would naturally justify the assumption of such a relation. In the advanced stages, secondary anemia would no doubt aid in the production of tachycardia and in isolated cases of young anemic individuals and chlorotic girls it is reasonable to presume that the anemia is a causal factor even in the early periods of tuberculous disease.

When, however, we investigate the frequency of this symptom in forms of tuberculosis, other than pulmonary, we find that there is rarely if ever any mention of it, whereas in the pulmonary affection its occurrence has attracted uniform attention. This fact alone would justify us to seek a relation between the lungs and the heart not only for the occurrence of hypertrophy of the right ventricle or for its dilatation which is generally recognized, but also for the earlier manifestations of cardiac insufficiency before structural changes in the heart muscle are as yet present. The difference here is only one of degree, and in either case the local processes in the lungs appear to me to stand in intimate relation.

The time of the appearance of cardiac symptoms may be influenced by various contributory conditions of which the small heart, when present, is undoubtedly one. In addition to or apart from it the local processes in the lungs can also have an influence in an early stage, even when physical signs are absent and when it may happen that the eruption of tubercles occurs chiefly along the course of small blood vessels and capillaries over considerable areas, and when this process is attended by obliterating arteritis. In the advanced stage, with progressive emaciation and atrophy of the muscular structures, tachycardia is readily accounted for both by the presence of increased obstruction in the lesser circulation and by the lack of power of the heart to compensate it. Under all circumstances my clinical study of the subject has convinced me that the occurrence of simple tachycardia or its combination with hypertrophic or degenerative changes in the heart muscle is further influenced by external causes in any stage of the disease, through and by which the heart is called upon for increased effort. I refer here more particularly to physical labor and exercise, the causal relations of which have been overlooked by most writers on the subject. Even clinical observers rarely base the regulation of exercise in phthisis upon other considerations than the influence which it has upon fever. On the contrary, patients without fever who are still in good nutrition are commonly advised to exercise and are often permitted to indulge in sports, mountain climbing, horseback riding, etc., without a thought of the effect of physical exertion upon the heart and without the slightest control of its influence upon the cardiac functions as expressed by the frequency and quality of the pulse. This is the more strange since it is well known that overexertion can be followed by acute or chronic heart strain in persons who are in good health and are free from pulmonary obstruction. For this fact Frye and Krehl[30] have supplied experimental proof. Schott,[31] in a more recent experimental study of the subject, found in healthy men that so long as muscular exercise did not induce decided shortness of breath the heart maintained its normal position and was not disturbed in its function. When, however, decided shortness of breath was induced by the exercise, its continuance for a few minutes longer caused demonstrable displacement of the right border of the heart to the right and of the apex beat toward the axilla, while the blood pressure fell from 10 to 20 m.m. Hg. With suspension of exercise these effects gradually disappeared, but in some instances not until after two hours. Schott has also related a number of clinical cases from his practice in which acute dilatation after more or less severe physical exertion occurred in healthy individuals. Still more recently Masing[32] has contributed a study of the subject, in which he also shows the relation of increased pulse rate and heart strain to muscular exercise, with coincident fall of the blood pressure, and my father called attention to the necessity of controlling the pulse in the regulation of exercise in phthisis as long ago as 1889.[33]

In order to show the relation of physical over-

exertion as one of the factors contributory to the more ready occurrence of failing heart action in the course of phthisis, as well as for a basis for the consideration of the prognosis and therapy of tachycardia, I have made an additional study of the clinical material of the Winyah Sanitarium, included in a recent report of 261 cases of pulmonary tuberculosis treated during the last two years. Excluding the cases with evidence of more or less dilatation already existing, 2 cases of chronic pericarditis, and likewise 13 other cases in which the advanced stage of the disease and emaciation could alone account for the presence of persistent tachycardia, there remain 60 cases in which the cardiac function was disturbed in a greater or less degree. In 25 of these the pulse rate was not only persistently 20 to 30 beats above the normal, but its rapidity was markedly out of proportion to the general condition of the patient, the local changes in the lungs, and to such degree of fever as existed. In 23 other cases tachycardia became evident only in response to slighter degrees of physical exertion or to psychical influences, or to both, while in 12 cases it was paroxysmal, occurring without apparent exciting cause, sometimes when the patient was at rest, or sometimes when awakening from sleep. According to the statements of these 60 patients, overexertion had been a contributing factor in 35 cases, or in 58.3 per cent. Twenty-nine of them had taken excessive physical exercise prior to their admission to the Institution, and this they had done, as a rule, with a view of increasing their strength in their efforts to overcome the disease. All of these patients had at various times, by their exercise, induced decided shortness of breath and marked fatigue, while in a number of them palpitations of the heart had occurred under physical strain for the first time. Three other patients had followed athletic sports before and for some time after the occurrence of symptoms on the part of the lungs; another was a professional athlete, while one claimed to have induced palpitations for the first time by running and another by lifting a heavy trunk. As to the other 25 cases, tachycardial attacks appeared to have followed pregnancy and labor in one. They occurred after hemoptysis in 3, in connection with indigestion in 8, followed prolonged periods of fever in 7, and seemed to stand in relation to psychical influences in 2. In the remaining 7 no definite cause could be assigned.

If the statements of these patients have all been reliable, it appears that physical overexertion was the immediate cause of heart strain in more than half of the cases studied, and it follows that if they had been properly controlled the occurrence of this unfavorable complication could have been prevented.

Of the prognostic import of tachycardia in the course of phthisis, the therapeutic results in the 261 cases above referred to are highly indicative. For the entire number the records of the institution show 153 apparent recoveries, or 58.6 per cent., and 37 radical improvements, or 14.2 per cent., making in all 72.8 per cent. of satisfactory results. However, in 173 cases in which the circulation was not at fault in any respect, the results were much better, there being 133 cases apparently cured, or 76.9 per cent., and 27 cases greatly improved, or 15.6 per cent., with a total of 92.5 per cent. of satisfactory results. On the other hand, in 88 cases with tachycardia, in which are included those in which more or less dilatation of the right ventricle had occurred, one case of pulmonary stenosis and two of chronic pericarditis, there were only 20 recoveries, or 22.7 per cent., and 10 radical improvements, or 11.4 per cent., *i.e.* a total of only 34.1 per cent. of good results.

It might be suggested that these striking differences depend not simply upon the presence or absence of tachycardia, but rather upon the advanced stage of the local pulmonary disease in the cases with tachycardia, as compared with those without it. That this is not true, however, becomes evident from a classification of the 261 cases, according to Turban's method, which is based chiefly upon the amount of pulmonary tissue involved. According to this classification, I find that the cases would appear by stages respectively as follows:

Turban's Classification in Stages of Phthisis.

88 cases with tachycardia:
First stage, 21 = 24.0 per cent.
Second " 33 = 37.3 " "
Third " 34 = 38.7 " "

173 cases without tachycardia:
First stage, 36 = 20.8 per cent.
Second " 71 = 41.0 " "
Third " 66 = 38.2 " "

Thus in 21 cases tachycardia was already a symptom at a period when the local lung affection had not as yet made serious advances, a finding which accords with that of Roth,[34] who reports symptoms of palpitation in 111 of 500 cases of pulmonary tuberculosis in an early stage.

In the treatment of tachycardia in the course of phthisis, whether functional or already attended with degenerative changes in the heart muscle, all writers are agreed that avoidance of cardiac strain is the first condition to be complied with. Rest, therefore, as the therapeutic indication, implies a recognition of the detrimental effects upon the heart and circulation of physical overexertion, and likewise of the value of its prevention. But the prevention of heart strain is only possible through the observance of the frequency and quality of the pulse, especially before and after exercise, and likewise in the regulation of exercise the information thus attainable is absolutely indispensable. Without underestimating the value of controlling the temperature also, I may say that as the choice of two evils, I should prefer that a patient with a normal heart action should take some exercise, although his temperature was moderately elevated, than that another with normal temperature should do so if the exercise is followed by tachycardial attacks.

I have already stated that the control of the pulse in its relation to exercise in the management of phthisis is practically ignored, and this appears to be the case even in many special sanatoria for tuberculous patients. At all events but rarely is reference made to its importance. Thus Mackenzie,[35] in a paper recently read before the Harverian Society at London, stated that the pulse rate is of much less importance than the control of the temperature in the regulation of rest and exercise.

In the treatment of individual cases physical examination of the heart often affords valuable indications, while it also frequently aids in the earlier recognition of instances of heart strain, in which tachycardia appears only upon physical exertion, and in which at rest the pulse rate is not unduly rapid. I refer to cases in which the second pulmonary sound is heard as decidedly weaker in the second left interspace, near the sternum, than the combined aortic and pulmonary sounds as heard to the right; also to those in which there is a marked accentuation of the second pulmonary sound associated with decided epigastric pulsation, and in which, when the patient is at rest, no undue frequency of the pulse is observed. I believe that my experience justifies me in stating that the majority of such cases will show an inordinately rapid pulse in rela-

tion to moderate physical exercise, the one class suffering from deficiency in power of the right ventricle, while in the other the heart labors, even at rest, under excessive strain. In such cases the suspicion should at once arise that uncontrolled exercise is liable to be followed by injury, and for this reason exercise should be regulated by observations of the pulse, and kept within safe limits at all times, even though the patient is still well nourished and is practically free from fever.

Patients in whom tachycardia is a constant symptom while at rest should be kept in a recumbent position, even though no evidence of dilatation is present, and it goes without saying that the more nearly absolute the rest, the greater are the prospects of overcoming this symptom. The disregard of this indication will sooner or later lead to disaster, either on the part of the heart directly, or by the advent of advancing destructive changes in the lungs sufficiently often that recovery or radical improvement will constitute a rare exception. When once the symptom of constant tachycardia has been overcome, properly supervised exercise, combined with general hygienic management, becomes a curative measure for patients with a weak second pulmonary sound, except in those cases in which, by rapid progress of the disease in the lungs and advancing obstruction in the pulmonary circulation, an unfavorable course is conditioned.

In cases in which the right ventricle is laboring under tension, and tachycardia is not a symptom when at rest, exercise cautiously regulated to prevent any undue strain is rather calculated to prevent degeneration of the heart muscle and to favor the occurrence of hypertrophy, if not already present. But in these cases also the heart is liable to yield to strain under the most careful management, when intercurrent pulmonary inflammations, extension of the tuberculous disease in the lungs, pleural effusions or marked fever of long duration supervenes.

In addition to rest or limited exercise, as indicated in the individual case, the diet should be given especial attention. In many instances I have observed attacks of tachycardia to follow the ingestion of large meals or unsuitable food. The amount of food taken at a time should, therefore, be small, and the intervals of feeding more frequent. Albuminous foods should predominate in the diet, and articles liable to cause fermentation should be avoided. Daily evacuation from the bowels should be secured. Such patients should be brought into the open air whenever possible, and in cases in which the maintenance of the recumbent position is essential, the patient may be transferred to a cot without rising, and carried thereon to an open piazza, or the bed may be brought near to an open window.

To favor the cutaneous circulation, cold rubs in suitable cases may be employed and massage may be resorted to. In distressing attacks of palpitation an ice bag applied over the heart frequently affords relief. Alcoholics and tobacco are strictly to be prohibited. The usual cardiac tonics are only occasionally of benefit, and often appear to do harm by deranging the digestive organs.

The general treatment of actual or suspected dilatation must be carried out upon the same principles. In addition to the measures which have been mentioned, digitalis should be administered. In dilatation it appears to do more good, but it rarely proves as effective as in cases in which there is no obstruction in the pulmonary circulation. In instances in which the power of the heart fails rapidly or suddenly, diffusible stimulants may be employed with a view of prolonging life. Indirectly, all measures which otherwise tend to arrest the progress of the disease in the lungs, or favorably to influence its symptoms, and especially the fever, or which tend to reduce the obstruction of the pulmonary circulation, will, of course, prove of benefit as regards the heart and circulation.

In conclusion, I wish to call attention to the analogy between the relation of the heart and circulation to the local disease in the lung in acute pneumonia and in chronic pulmonary tuberculosis. According to my conception, this relation differs chiefly therein, that the pulmonary obstruction develops rapidly in the one and more slowly in the other. By reason of this difference much more can be done to conserve or increase the power of the heart in phthisis than is possible in acute pneumonia. In both affections the condition of the heart and circulation has a great influence upon the prognosis, and often determines the outcome of the disease. If I am correct in this deduction, it follows that close observation of the circulation in the course of phthisis is imperative, and we must regard as a signal of danger a weak second pulmonary sound, just as every careful physician does the advent of this phenomenon in cases of acute pneumonia.

THE RELATION OF ETHMOIDAL INFLAMMATION TO ASTHMA.

By HENRY COGGESHALL, M.D.,

NEW YORK.

Asthma is a name given to paroxysmal difficult breathing. The disease is inflammation of the mucous membrane in the ethmoid cells. An irritation of branches of the trigeminus or olfactory nerves causes an altered activity in the medulla, that is to say, in the center of respiration. The result in the bronchial tubes is a vasomotor disturbance or contraction of muscles, or both. Chronic bronchitis, or emphysema, or a dilated right side of the heart, are not asthma. They are sequels to asthma of severity and long standing.

The disease occurs at all ages; its beginning is most often in early childhood and youth, and less frequently in advanced years. It is not commonly recognized in the earlier ages.

The confusion in regard to asthma has been very great. When one author claims sixty per cent. of cases cured and twenty per cent. more much improved, by the use of the galvano-cautery upon the nasal septum, and others get good results by removing obstructions to free nasal breathing, while the general belief is, perhaps, that diseases of the nose play little or no part, there is great need of a better understanding or of some reasonable hypothesis.

I wish to defend my hypothesis or working theory. All forms of hayfever and kindred diseases I should class as one with asthma. It would commonly be accepted that nasal polyps may be a cause of asthma and that their removal may cure the disease. The result is not always obtained because the inflammation of the ethmoid cells, *which has caused the polyps,* may or may not have been cured by their removal. When the septum has been cauterized in the neighborhood of the ethmoidal turbinate, which is the procedure of Francis, that is attended by such brilliant results, a feature of the ethmoidal inflammation has been treated. The perpendicular plate of the ethmoid bone, which is the upper part of the nasal septum, is a part of the ethmoid cells and an inflammation of the region is a very common sign of general ethmoidal inflammation, though it has never been so described.

Many diseases of the nose may be indirect causes of ethmoidal inflammation, and thus of asthma. In the child the pharyngeal tonsil is the most frequent cause of repeated inflammations of the nasal mucous membrane. The removal of the tonsil restores the nose to health and cures the asthma. Nasal obstruction is the commonest cause in the adult. Removal of this condition may cure the asthma.

When breathing is free through each nostril, and no polyps and no pus are found in the nose, is it therefore free from disease? By no means. A chronic inflammation may be present which becomes acute from the most varied causes. That is the usual "taking cold." These varied factors are the contributory causes of asthma. Errors of nutrition, errors of diet, gout, obesity, lymphatism, impure air and poor circulation are such causes. To these add direct irritants to the nasal mucous membrane, such as various pollens, emanations from animals, dust, smoke, and many others in the cases of the sufferers from periodic asthma.

The question of heredity has been always one of the puzzling things in connection with asthma. But as much as external features in a family are found in resemblance one to another, so much, or even more, are found resemblances in structure of noses and throats with the tendency to the same diseases. Not only that, but the members of a family will generally suffer from the same eruptive diseases, whooping-cough and influenza, which especially cause diseases in the nose and throat. The diseased conditions that have been mentioned as contributory causes of asthma: gout, obesity, lymphatism, and even errors of diet, are inherited. As with deafness, tendencies thereto are inherited. The influence of the emotions, fear, fright, anger; and of the imagination, as when artificial flowers have produced an attack of periodic asthma, have been among the mysteries of asthma. If the emotions can arrest digestion, or stop the heart, or precipitate an attack of gout, it is not difficult to conceive how they may cause an attack of asthma in a sufferer from it. They do not cause the disease. The sudden onset of an attack of asthma, most frequently in the night, is explainable by the influence of the digestion and of atmospheric changes upon the diseased nasal mucous membrane.

The same conditions to all appearances may exist in the ethmoid region without asthma. It is equally true of many diseases in which the etiology is considered certain. Thirteen years of special work in nose and throat diseases, and a personal acquaintance with the disease, confirm my theory.

The treatment of asthma is the treatment of the contributory causes as well as of its anatomical cause. And, unfortunately, it must be that of intractable sequels to the disease as well. A great need is to prevent asthma. Two diseases which cause a predisposition to it are whooping-cough and grippe, or specific influenza. Both particularly cause inflammation of the ethmoid cells and leave the region more prone to recurrent inflammation.

Slight degrees of asthma are very common. It is oppression in breathing, air-hunger, *disturbed sleep* from this cause, *sneezing*, which require attention before wheezing, and sonorous and sibillant râles are present.

The inflammation of the mucous membrane in the ethmoid cells may be cured easily and quickly, and asthma disappear as if by magic, or it may be long and difficult and taxing to resources and patience. If a gouty condition or alcohol, for examples, are contributory causes, the local treatment may fail until those factors are eliminated. Prevent the recurring inflammations and shorten their duration, that is, prevent taking "colds," and treat "colds." The digestive tract is the clue to very many. Overdressing indoors is another. One weight of underwear for all the year is to be recommended.

The treatment of the ethmoidal inflammation is to be conceived as that of an inflamed mucous membrane in a structure somewhat resembling a honeycomb. It is not to be conceived as something to remove or to treat with heavy hands. I cannot see that the galvano-cautery has any place in the treatment. It is dangerous in this region, and while the swelling of the membrane which Francis cauterizes is a barometer in asthma, it is only a part of the more general ethmoidal inflammation.

It is sometimes necessary to remove the anterior end of the ethmoidal turbinate. This, it should be remembered, is a part of the ethmoid cells. We sometimes find one or two ployps lying like peas in a pod within the shell of bone. The bone throughout the ethmoid cells is often reduced to the thinness of paper by pressure within them. The usual treatment is to nurse the inflammation into a state of health. Restore the function of the region, a part of which is the drainage of frontal, maxillary, and sphenoidal sinuses. Puncture the cells when it seems necessary, to convert two or more into one. It is not drainage nor the making of space for the ethmoidal turbinate that should be the end in view, but the control of chronic inflammation.

A DIFFICULT DIAGNOSIS IN A CASE OF ABDOMINAL PREGNANCY.

By W. S. LANGFITT, A.M., M.D.,
PITTSBURG, PA.
SURGEON, ST. JOHN'S GENERAL HOSPITAL; INSTRUCTOR IN CLINICAL SURGERY, WEST PENN MEDICAL COLLEGE.

Our textbooks are filled with explicit directions for the diagnosis of abdominal pregnancy, and still we fail. It is simply out of the question to discover a fetus, outside of the uterus, every time it should happen to be there. All we can hope to know is that there is a disturbing element in the patient's abdomen which makes her feel unnatural. This unnatural feeling should be especially heeded by the physician and after all normal conditions (ordinary pregnancy), are excluded, he should hasten to discover the cause. We should not procrastinate, but have the abdomen opened at once when all speculation will be out of the question, and the proper treatment can be administered early. Prompt diagnosis and operation must be performed to have the proper results in these cases. It is a mistake to delay in opening the abdomen. Simple abdominal section kills practically nobody and throws much light on obscure abdominal maladies. The maxim "he who hesitates is lost," fits exactly in these conditions.

The report of the following case will show the fitness of my remarks:

Mrs. B., admitted September 12, 1904. Occupation, housewife; aged 37 years. Family history negative. The patient has had the ordinary diseases of childhood with perfect recovery. She began menstruating at the age of 13. Previous to an operation five years ago (curettage), her periods lasted one week; now they last only five days, and are usually profuse, but accompanied by no pain of any moment. The patient has had a leucorrheal discharge ever since her marriage. The bowels are usually constipated, and she suffers with retention of urine at times. She was married fifteen years ago, and has given birth to five children, the oldest being 14 years old, the youngest, 2 years old; one died in infancy. The labors were usually difficult. Instruments were used in the first, third, and last confinements.

The patient menstruated last in November, 1903. She had most probable signs of pregnancy. She says that she felt life about the sixth month. At the time her pregnancy should terminate naturally, she experienced distinct labor pains. The family physician was called and remained with her most all the night. Her labor pains ceased, and after these no pains were felt. This occurred one month ago.

The patient entered the hospital walking, September 12, 1904. The temperature was 101° F., pulse 96 (signs of infection). On examination per vaginam, the os uteri could be palpated only with great difficulty; it seemed soft and patulous, and was situated high up, almost on a level with the symphysis pubis. The uterus seemed to be drawn backward and upward to a remarkable degree. In the cul-de-sac was felt a mass which seemed to be the head of a child. The abdomen was enlarged, presenting the ordinary appearance of that of the pregnant woman. A very large mass could be felt, but the fetal heart sounds could not be elicited. The mass simulated the characteristic feeling of an ovarian cyst. The breasts were enlarged.

Operation on September 13, 1904. An incision was made in a median line about 5 inches long. The umbilicus was at the center of the incision. On opening the peritoneum, the uterus was found to be but very slightly enlarged, and pushed well up in the abdomen by a very large mass filled with fluid. This (the amniotic sac), occupied the whole pelvic cavity, including the cul-de-sac, and was attached to the right Fallopian tube. There were numerous adhesions between the transverse colon and the mass. The mass was also very adherent to the posterior surface of the uterus. After isolating this mass from the intestines and the uterus, the right Fallopian tube was ligated and the sac and tube were removed. Hemorrhage was profuse from many bleeding points of adhesion. These bleeding points were closed by ligature and the uterus suspended to the abdominal wall. A drain of iodoform gauze was placed through the cul-de-sac into the vagina and the abdomen was closed. The mass removed weighed nine pounds, and contained a full-term dead fetus and the placenta. The fetus alone weighed six pounds. The patient suffered severely from shock during the operation, and one quart of physiological salt solution was injected subcutaneously, four ounces of whiskey being given hypodermically. The patient was then put to bed in the Fowler position, and was given a saline enema every two hours. Strychnine and whiskey were given hypodermically when needed. At 8 P. M., eight hours after the operation, the temperature was 102°, pulse 120.

September 14, 8 A. M., temperature 101°, pulse 102. Bowels have moved twice. At 8 P. M., temperature 100°, pulse 102.

September 16, 8 A. M., temperature 99.2°, pulse 88. Patient slept well, but there is some distention of the abdomen. Drainage was removed, as all discharges had ceased. 8 P. M., temperature, 102°, pulse 104.

September 17, 8 A. M., temperature 100.2°, pulse 112. Bowels are moving every two hours, the abdomen is distended, and the patient is vomiting. 8 P. M., temperature 100.4°, pulse 120.

September 18, 8 A. M., temperature 102°, pulse 130. Bowels moving, patient vomiting. 8 P. M., temperature 100°, pulse 120.

September 19, 8 A. M., temperature 103.4°, pulse 130. The bowels are moving and gas is being expelled. 8 P. M., temperature 103°, pulse 134.

September 20, 8 A. M., temperature 103.6°, pulse 160. Patient is vomiting very often. 5 P. M., temperature 106.4°, pulse 160. 5:40 P. M., the patient died.

As will be observed from the history of this case, the fetus was dead and fast disorganizing. The skin was peeling off the body, showing that the child had been dead some time. The patient's temperature on admission would show that she was absorbing septic material. Valuable time was lost before she reached the surgeon's hands. I firmly believe had she been operated upon before infection had begun, and when she had a normal temperature and pulse, she would have recovered. This case is certainly a valuable lesson.

512 Bijou Building.

A CASE OF HEROINE HABIT.

By CHAS. E. ATWOOD, B.S., M.D.,
NEW YORK.
ASSISTANT IN NEUROLOGY, VANDERBILT CLINIC, NEW YORK, AND FIRST ASSISTANT PHYSICIAN, SOCIETY OF THE NEW YORK HOSPITAL, BLOOMINGDALE, WHITE PLAINS, N. Y.

Much has been written and said concerning heroine as a perfectly safe anodyne and hypnotic, lacking the objectionable features of opium and morphine. Cases of heroine habit are, as yet, comparatively rare, but they are apt to increase in number unless we are more cautious in its prolonged administration, especially to neurotic individuals, *e. g.* as a hypnotic, or as an anodyne in chronic coughs, neuralgias, pains of rheumatism, recurring headaches,

etc. It has been urged as a substitute for morphine in the treatment of morphine habit; but to me this suggestion seems fallacious, as heroine is itself an opium derivative, viz., the diacetyl of morphine, and the habit it may itself induce is really an opium habit. The condition brought about by the prolonged use of heroine as a habit, in the case to be described, was similar to the condition I have seen in many cases of opium habit, but less severe in degree; and the abstinence symptoms induced by the withdrawal of the heroine resembled those in the morphine habitué when morphine is withdrawn. The symptoms in the morphine consumer may be more profound on account of its greater action in impairing excretion and thus inducing possible autotoxemia.

Insanity, independent of the drug psychoses, is very rarely produced by opium (or its derivatives) *per se*—more rarely than by cocaine. The case described below was not in an insane woman, although she sought asylum treatment.

The patient was an educated and refined married woman 29 years of age. She was of neurotic heredity and disposition. Her mother had epilepsy, two paternal uncles were inebriates, and her father used morphine for a year and a half for the pain of rectal cancer. She herself contracted the morphine habit ten years prior to admission, but was cured of it, and never resumed it afterwards. She was operated on for appendicitis a year and a half prior to admission and heroine was administered hypodermically afterwards for pain. The effect of the drug, she claimed, was extremely pleasant and exhilarating. She ascertained the name of it, and having been assured by the physician, she said, that it was perfectly harmless, and that habit could not be formed, she continued its use, on the sly, when it was no longer needed, taking, she stated, from 2½ to 4 grains *per diem,* hypodermically, in divided doses. After a time it began to affect her health. She became thin, neurasthenic, and debilitated, her digestion was disordered, and she claimed she could not sleep, eat, or do anything without a daily resort to the drug. After taking it, she always felt as if she "could do anything," she said.

On admission she weighed 50 pounds less than normally, and was anorexic and neurasthenic; she had dilated pupils, slightly coated tongue, normal temperature, and pulse of 100. Urine contained excess of phosphates and had sp. gr, 1030. There was a systolic murmur of the heart.

Heroine was immediately dithdrawn. The patient was insomnious and developed a diarrhea with intense colicky pains and was with difficulty persuaded to remain. The pains were partially relieved by chloroform and ginger internally. The third day after admission heroine gr. 1-20 was administered with salol, twice, and the same dose given that night with a mild hypnotic. The pains ceased with the first dose of heroine, gr. 1-20, and did not again recur. Patient slept only an hour that night. The next night she was given a hypnotic, and slept three hours. She sat up on the fourth day, read and conversed cheerfully, and did not again display any irritability or distress of mind, and said she had no further desire for the drug. A mild hypnotic was continued each night until the tenth, when she began to sleep normally, and on the thirteenth day after admission she insisted on her discharge, although she was still neurasthenic, as indicated by some remaining tremors of eyelids, hands, and tongue, and had not as yet regained much weight.

The treatment in this case was symptomatic, sustaining, and tonic with eliminative baths, massage, etc. Residence in a country house, with a nurse, was urged, and I learned subsequently that the advice was followed. I saw the patient six months after discharge and found a handsome, healthy-looking woman, and was told by the husband that there had been no recurrence thus far of even a desire for the drug.

In future, if I have another case, I shall not withdraw the drug at once, but give a very minute dose p.r.n. for a time, to prevent, if possible, some of the abstinence symptoms, *e. g.* the distressing abdominal pains and the insomnia.

CACTUS GRANDIFLORUS.

By FINLEY ELLINGWOOD, M.D.,

CHICAGO, ILL.

For many years digitalis has been accepted as the classic heart remedy, but there is another which is but little known to the profession at large, which is in every way superior to digitalis, and that remedy is cactus grandiflorus. This agent, the night blooming cereus, is native to the West India Islands and Mexico. The medicine is prepared from the stems and the flowers.

In its administration a small dose will often accomplish all the desired results, and observers unite in the statement that large doses are in no way better than those of from two to five minims of the fluid extract. The remedy exercises a direct influence over the sympathetic nervous system. It restores normal action to the heart, by acting directly upon the cardiac plexus, regulating the functional activity of the heart. It certainly improves the nutrition of the heart to a very perceptible extent, and we have noticed the entire removal of progressive murmurs after its continued use. It increases the contractile power and energy of the heart muscle, through the cardiac ganglia and accelerator nerves. It increases the musculomotor energy of the heart, elevates arterial tension, increases the height and force of the pulse wave. It is the heart tonic, *par excellence,* as it produces stimulation from actually increased nerve tone, through improved nutrition of the entire nervous and muscular structure of the heart. It produces no irritation of the heart muscle like strophanthus, or gastric irritation like digitalis, nor is its action cumulative.

When the following indications for its administration are present, it will act promptly and with great satisfaction to the prescriber: When there is an irregular pulse, due to feebleness of the heart's action, with dyspnea, weight and oppression in the chest, or when there is violence with irregularity of the heart's action, which depends upon atonicity or enervation, and especially when there is a sensation of constriction, as of a band around the heart or around the chest, this agent is indicated.

In cases of progressive valvular inefficiency, when the heart muscle is enfeebled, or when there is mitral or aortic regurgitation, from any cause, with atonicity, this remedy should be prescribed, and persisted in. It is also valuable in functional irregularity of the heart, especially if due to gastric irritation. It soothes irritability of the stomach and imparts tone and improves the function of digestion, in marked contrast to digitalis.

The following precautionary statement, however, should be made: When there is violent heart action or persistent palpitation from increased tonicity, or in the presence of a temporary exaltation of nervous or muscular tone, this agent is contraindicated. It will certainly aggravate the conditions present. Atonicity is the keynote of its administration.

The writer's experience with this remedy years ago caused him to come to the conclusion that the agent exercised a special sedative influence when with irritable, irregular, and feeble pulse there was an elevation of temperature. He was subsequently convinced of this fact by further observation, and lately finds excellent confirmation of his conclusions in the opinion of Rubini of Naples, who claims that it is almost the counterpart of aconite in its action, differing in that it increases the strength and tone of the nerve centers instead of paralyzing them, as large doses of the latter agent do.

Given a condition in which there is a rapid and feeble pulse, a weak heart, and weak and exhausted nervous system, cactus in small doses, frequently repeated, is a true sedative.

Because of its influence in improving the nutrition of an enfeebled heart, and through this influence in restoring the normal functional operations of the heart, the agent is specific in certain cases of subnormal temperature. In many cases in which its influence has been carefully observed, it has operated more directly, more quickly, and more satisfactorily than strychnine or digitalis, and its influence has been permanent.

Given in endocarditis or pericarditis, when these disorders are the sequelæ of exhausting disease, the results of cactus are most gratifying. It will relieve the bloated condition of the countenance, the dyspnea, and general distress, and will control the rapid, feeble, or fluttering action of the heart. In vulvular incompetency, due to muscular weakness, as a result of pneumonia, typhoid fever, or other severe and prostrating diseases, as well as in the feebleness of the heart's action in protracted convalescence, it serves the double purpose of a heart tonic and nerve tonic.

In that now quite common heart disorder, which results from the excessive use of cigarettes, we certainly have no agent that can be relied upon for promptness, efficiency, and permanency of action that will in any way compare with cactus. Any combination of heart tonics that we may be inclined to make will not compare with the action of this single remedy.

The Therapeutic Value of Relaxing Climates.—Leonard Williams declares that the practice of climatotherapy and the principles which underlie it are greatly neglected. He calls attention to the disadvantages of prescribing a "bracing climate" in many cases. The combination of meteorological factors which constitute a bracing climate consist of high altitude, dryness, and rarefaction of the atmosphere, free exposure to sun and wind, and moderate rainfall. If the humidity is low there will be great and sudden variations of temperature; if the humidity is high, the variations are slight and gradual, but the climate is no longer bracing. A climate cannot be dry and equable at the same time. A bracing climate is characterized by extremes, and its physiological effect is one of stimulation. That which is a stimulant in normal states is apt to become an irritant in abnormal states. The meteorological factors which combine to produce the typical relaxing climate are moderate, if any, elevation, moderate exposure to wind, full exposure to sun, and a high humidity, with its consequent equability of temperature. Such a climate is possessed of a very much wider therapeutic range than that whose subjective effects are agreeable. Few invalids of the chronic type bear stimulation well. Some invalids of the subacute type bear it well and some do not. But sufferers from chronic pulmonary troubles, from chronic renal troubles, from chronic heart disease, and chronic nervous disease, all demand a sedative rather than a stimulating regimen. There is no type of climate which is per se suitable to pulmonary tuberculosis. Each patient must be treated according to the stage and type of the complaint, and his individual characteristics must always be considered. Emphysema enjoys considerable subjective amelioration in a relaxing climate. There is no class of cases in which more satisfaction is to be derived from the advice of a suitable climate than those of chronic nephritis. The great essentials are warmth and equability. For these cases Madeira and the Canary Isles offer great advantages. In a bracing climate chronic nephritis patients are peculiarly liable to cardiac troubles and cerebral hemorrhage. Bracing conditions tend to raise the blood pressure, while relaxing conditions reduce it. For such reasons bracing climates are definitely contraindicated in all chronic diseases of the heart. In the treatment of the degenerative processes which affect the central nervous system bracing climates have no place. Tabes, disseminated sclerosis, and primary lateral sclerosis are favorably influenced by a warm, relaxing climate. In cases of neurasthenia and hysteria, temperamental conditions largely determine the choice of climate. Other therapeutic aids, such as baths and waters, should be considered in relation to climate. The writer concludes with a plea for a truer and fuller estimate of the therapeutic powers of relaxing climates.—*The Edinburgh Medical Journal.*

Endemic Enlargement of the Os Calcis; Prevalence in Formosa.—James L. Maxwell, in discussing this disease, states that it is rare, as he has seen only six cases in all in Formosa. He gives the essential features of this affection as follows: Slight enlargement of the posterior third of the os calcis; the enlargement, though slight, is quite unmistakable; constant pain of a dull nature, increased by pressure and by movement; its occurrence in young males. All of the writer's cases have been in boys from 20 to 25 years of age. There was no history of syphilis in any case. Five of these six cases were afflicted in both feet. The drugs used seemed to offer no relief, and there is little tendency to spontaneous cure as far as the writer has observed. He operated on two of the cases. In one he divided the periosteum freely, but this treatment did not appear to offer much relief. In the other case, which was the severest he had seen, he cut down, as before, from the other side of the heel and drove a ¼-inch trephine through the bone to the inside, removing the disc separated. There was wonderful relief from this operation. The pain disappeared from the heel, and when the wound was quite healed the writer operated upon the second foot in the same way. The result was not quite so striking in this second operation, but it afforded the patient great relief nevertheless. The patient, who had been practically incapacitated from work by pain and difficulty in walking, gradually regained the power to walk about with complete comfort. He was then lost sight of. The writer states that the patient's themselves could never suggest any cause for the onset of the pain, which they were never able to date exactly, as it seemed to come on very gradually.—*The Journal of Tropical Medicine.*

The Choice of Operative Method for the Removal of the Hypertrophied Prostate.—L. S. Pilcher analyzes the literature and statistics of the subject as exploited in recent years. He finds that as modifying the perfection of results we may have impotence, urinary incontinence, epididymitis, orchitis, fistulæ, and urethral stricture. He then discusses each one of these sequelæ in detail, considers the indications and contraindications for operation, and takes up the treatment of the patient preliminary to operation. His choice is, as a rule, for that method of operating in which a free transversely curved incision is made through the perineum through which the prostate is fully exposed, followed by systemic incision into the substance and subsequent enucleations largely under the guidance of the eye. The general ends to be striven for are to remove the obstruction without undue prolongation of manipulation, with as little loss of blood as possible, and with a minimum amount of injury to the urethra, bladder, rectum, and ejaculatory ducts. Thereby we lessen mortality and consequent infirmities.—*Annals of Surgery.*

MEDICAL RECORD.

A Weekly Journal of Medicine and Surgery.

THOMAS L. STEDMAN, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 FIFTH AVENUE.

New York, June 3, 1905.

TYPHOID FEVER IN NEW YORK.

THE New York City Department of Health, during the past year, has been conducting an investigation to determine if possible some of the factors in the causation of typhoid fever in the Borough of Manhattan. To each physician who reported a case of the disease a circular letter was sent, which included among other things the following questions: 1. Was the patient an occasional or habitual consumer of raw milk? 2. Was the patient an habitual consumer of raw oysters? 3. Was the patient out of the city within four weeks of the onset of the attack? 4. Was the patient directly exposed to infection from another case of typhoid fever? When cases were reported by institutions inspectors were sent to obtain the same data. The total number of cases reported was 1,786, as against 2,334 the previous year.

Of these 1,786 cases 464 were not found at the addresses given, were ascertained not to be cases of typhoid fever, or insufficient data were obtained. As the reports from the remaining 1,322 were received, each case was plotted upon a large map of the borough by means of different colored tacks, which indicated not only the location of the case, but also the most probable source or sources of infection according to the information received. The map is very interesting in itself to the student of communicable diseases, and the facts learned may prove of considerable value in determining the cause of typhoid fever in this city.

In 351 cases, or 26.4 per cent., it was impossible to determine any definite source of infection, *i. e.* the patients were not consumers of raw milk or oysters, had not been out of the city within four weeks, and had not been exposed directly to infection. In 210 cases, or 15.8 per cent., the only apparent source of infection was in the fact that they had been out of the city and might have drank contaminated water. The history of 378 patients, or 28.6 per cent., showed that they were consumers of raw milk. The reports of 203 cases, or 15.3 per cent., showed that they had not only been out of the city within four weeks, but were also consumers of raw milk. The habitual consumers of raw oysters alone were only 22, or 1.7 per cent., while 44, or 3.3 per cent., were consumers of both raw oysters and raw milk. Direct exposure was considered to be the probable cause in 39 cases, or 2.9 per cent., while 14, or about 1 per cent., were directly exposed outside the city, and 61, or 4.6 per cent., were not only direcly exposed to infection, but were also consumers of raw milk.

These figures should comfort the oyster eaters, for only 66, or 5 per cent., of these patients were consumers of raw oysters, and of these 44 were also consumers of raw milk. Milk drinkers, on the other hand, cannot derive as much comfort, for in 686 cases, or 51.7 per cent., raw milk had been a part of the dietary. While it would not be fair to assume that infected milk was the cause of the disease in all these cases (for in 308 there were also other possible sources of infection), yet the fact remains that more than half of those affected were milk drinkers. Moreover, the distribution of the cases presents some very interesting features. A glance at the map shows a very apparent grouping of cases about centers, and this is particularly true where the probable cause of infection was milk, the natural inference being that the milk was obtained from the same source.

Certain localities and streets were particularly exempt. Fifth avenue from Washington Square to 120th street showed only four cases. This section is occupied by private houses, hotels and boarding houses of the first class, and most of the milk consumed is probably obtained from the best and most carefully inspected dairies, and the sanitary conditions are superior to those in many other localities of the city. In contrast, it was found that 359 cases, or more than 27 per cent., occurred below Fourteenth street, and the most of those on the lower East Side, where a greater part of the milk is obtained from groceries.

The theory that local conditions are a factor to be considered was strengthened by the apparent immunity of certain sections, while in adjoining sections the disease was prevalent. Thus between Madison and Lenox avenues, from 124th to 130th streets, there were only four cases, while from 131st to 135th streets, between the same avenues, there were 21 cases. The avenues appeared to be singularly free from the disease, the majority of the cases being located on the narrow cross streets, and a very large proportion of these were located near the center of the blocks. These facts would seem to indicate that an abundance of fresh air, light, and sunshine are important factors in the prevention of typhoid fever, at least in the city.

The fact that in 351 cases of typhoid fever occurring in New York in 1904 no definite probable source of infection could be obtained, suggests the query whether the water supply of the city is up to the standard which ought to prevail, and whether a proper filtration plant ought not to be established. The installation of such plants in foreign cities has been followed by a marked decrease in the number of cases of typhoid fever, and the protective value of filtration has been abundantly demonstrated by comparative statistics in Philadelphia, where the supply of a portion of the city is filtered, while that of the remaining section is not.

THE MORTALITY FROM CANCER.

BY the aid of medical science it has been possible to check if not eliminate, in some instances, certain of the dread scourges of mankind, but prophylaxis, as applied to the subject of cancerous diseases, has not met with any marked success. The mortality still remains high, and it seems as if methods of prevention had been more or less sacrificed to means of operative and other treatment. It is, of course, nec-

essary that a more intimate knowledge of the etiology of the condition should be formulated before preventive measures can be instituted, but in this direction, progress has been doubtful, and we still await the word of the discoverer. The importance of the subject, from the social and commercial viewpoints, is shown by the interest which the life insurance companies have taken in the matter. In one of the largest of the German companies, which includes in its membership persons in all walks of life, the number of deaths from cancer during the fifteen years from 1885-1899, is reported to have been 7,081, or over ten per cent. of the total mortality.

P. Juliusberger presents a very careful study of these statistics in a recent number of the *Zeitschrift für Krebsforschung*. As the profession and laity have both become convinced that cancer is on the increase, this was one of the first points investigated. By comparing the number of deaths in three successive periods of five years each, a gradual but well-marked increase in the number was noted, from 3.7 per cent. to 8 per cent. in men and 11.4 per cent. to 12.9 per cent. in women. The second point in the investigation concerned the susceptibility of the two sexes, many claiming that a larger number of females are being constantly attacked, and it was found that the percentage of deaths was considerably greater among the women than among the men, those in the higher walks of life, moreover, being more often afflicted than the working women. The writer's figures also support the theory that heredity is an important factor in the production of the disease, from 1.8 per cent. to 3 per cent. of the total number of persons who died, having had near relatives afflicted with the disease. This figure is in all probability much too small, as there are numerous difficulties in the way of securing trustworthy histories. It has also been asserted that the increase in the disease is an apparent one, that the average term of life has become lengthened, and that as cancer is essentially associated with advanced years, the number of cases has only seemingly increased. The statistics under consideration show that 50 years is the most favorable time for the development of cancer, although 70 years may be looked upon as the limit, and that after this period there is a marked diminution in the number of fatal cases. The fact that people live a greater number of years than formerly does not therefore effect the question, but it is evident that at the present, death seems to take away patients suffering from cancerous disease, at least a decade earlier on the average than heretofore. In these statistics, gastric cancers were found to be the most frequent, almost 45 per cent.; then in succession those of the liver, intestines, esophagus, etc., those of the lips and nose being least often fatal. This investigation presents comparatively little upon which to base any theories as to the etiology of these malignant neoplasms, although from the purely statistical standpoint, the author's figures seem to point to heredity as an important factor.

The Relation of Alcohol to Insanity.

There can be little question that the excessive use of alcoholic stimulants is the bane of every civilized country. Despite the fact that undue addiction to alcoholic beverages is now recognized as the most important factor in racial degeneration, and that strenuous efforts are being put forth to stem the tide of drunkenness, but little headway has as yet been made towards this end. In Europe, with the possible exception of Great Britain, the alcoholic habit shows no signs of decrease, while in the United States more alcohol in various forms is consumed than ever before. The most effective means of abating the drink evil is by educating the people to a knowledge of the dire results accruing therefrom. Articles from recognized authorities which prove that drink is responsible for many forms of disease are valuable with this object in view. In an article in the *Post-Graduate* for May, Dr. Joseph Collins states that the intemperate use of alcohol is directly or indirectly the commonest cause of insanity. In fact, it is so nearly the sole cause that if alcohol could be stamped out for a century insanity would undoubtedly shrink in prevalence 75 per cent. This statement includes the assumption that alcohol is the most potent cause of poverty; that syphilis, from which a well defined form of insanity—general paresis—flows, has a direct relation to alcoholic intoxication; and that disharmonies of somatic and psychical development during the formative stages of the individual (*i. e.* pathological heredity) are more directly traceable to abuse of spirituous liquors than to any and all other causes. The writer points out, however, that it is not so much the amount of alcohol that a person consumes as it is the individual who consumes it that stands in causal relationship to insanity. The personal equation must always be considered in studying the effects of drink. Among the forms of insanity directly traceable to the abuse of alcohol are Korsakoff's psychosis, confusional insanity, pseudoparanoia, acute alcoholic mania, and pseudoparesis.

The Smoke Question Viewed From a National Standpoint.

In an address with this title, delivered before the Woman's Club of Cincinnati, and published in the *St. Louis Medical Review* of May 6, Dr. C. A. L. Reed reviews the subject from a financial, sanitary, moral, and ethical point of view, and narrates how Cincinnati has endeavored to solve the smoke problem. He states that in Cincinnati the possibility of smoke prevention has been practically demonstrated in steam generating plants that produce no smoke. However, these establishments, beyond demonstrating the possibility of doing away with the smoke evil, are too few in number to alter the general situation. The writer cites New York and Philadelphia in America, and Paris, Brussels, and Dresden in Europe as conspicuous examples of municipalities which have overcome the smoke difficulty. He lays down the following propositions as necessary to the solution of the smoke problem: 1. The development of an enlightened and quickened public sentiment on the subject. 2. A careful determination of all economic facts and an equitable adjustment of all conflicting interests involved in the controversy. 3. The determination and demonstration of all principles, practices, plans, and appliances for practical smoke prevention. 4. The formulation of a standard law which, with modifications to meet local conditions, can be adopted by all cities, and which will, therefore, result in the practically uniform regulation of the evil all over the country. In order to carry out these objects successfully, Dr. Reed suggests that a national antismoke convention be called in the near future.

A Time Limit for Papers.

The American Gynecological Society instituted a new ruling at the recent meeting at Niagara Falls, which seemed to be an improvement over the usual method of conducting the work of such bodies. These rules were that no abstracts should be read at the meeting unless the original paper was in the hands of the secretary, that abstracts or subjects announced by the Council would be limited to eight minutes, other abstracts to twelve minutes, and that no paper was expected to be read in full unless it could be read in the time mentioned. Under this rule only the prominent and important points of the papers were presented, time was not wasted with unnecessary details, and the gain gave more opportunity for general discussion. As the subjects were announced beforehand, it was possible for many who attended the meeting to be prepared to discuss them intelligently. While the time limit of eight minutes may seem very short, it is quite sufficient to give the pith of the work of any one man if the material is properly condensed. The fact that many more may take part in the discussion awakens a greater interest in the meeting not only on the part of those who discuss the papers, but also among those who come merely to listen, for they have the advantage of learning of the experience of a larger number of men on the questions brought up. Then, too, the reading of very lengthy papers is apt to be wofully tedious to a greater part of the audience unless the subject is presented in a masterly manner. On the whole, the plan seems to offer so many advantages that it would be worth while to make a trial of it more generally, as the tendency on these occasions is notoriously to too much prolixity.

Lupus Carcinoma.

The development of cancer in areas which have been the seat of lupus is of sufficiently frequent occurrence to attract attention. Norman Walker has discussed the question (*Scottish Medical and Surgical Journal*) from its pathological side. He thinks the carcinoma may originate in the equivalent of Cohnheim's buried epithelioma; portions of the proliferated epithelioma in the lupus process, having been cut off in the course of healing and cicatrization, become "cell rests" which subsequently undergo malignant degeneration. If this theory holds it is suggested that the curettage might cause portions of epidermis to be broken off and snared in the forming cicatrix and be responsible for subsequent malignancy. The cancer in lupus is papillomatous and does not involve lymph nodes, while that following *x*-ray treatment succeeds to a hyperkeratosis and rapidly involves gland structure.

Reaction of Colon Bacillus Toxin.—The action of the intracellular poison of the colon bacillus, the extraction and characteristics of which were described by Dr. Wheeler, has been studied by V. C. Vaughan, Jr. His conclusions are in substance as follows: 1. The colon bacillus produces a powerful poison when grown on artificial media. 2. It is intracellular in character and contained in both the living and the dead bacterial cells. 3. It can be separated from the other constituents of the cell only by chemically breaking up the latter. 4. The peritonitis occurring after intraperitoneal inoculation with the colon bacillus is due to the presence of the poison in a combined and not in a free state. 5. This intracellular poison causes a marked fall in body temperature. The poison of the colon bacillus apparently causes death by paralysis of respiration. 7. The intracellular poison is an essential group of the bacillus, and can be built up synthetically on proteid free media. 8. It is the poison causing death in animals inoculated with cultures of the living colon bacillus.—*Journal of the American Medical Association.*

News of the Week.

An Association of Laboratory Workers.—A new society called the Harvey Society, consisting of laboratory workers in New York City, has recently been established under the patronage of the New York Academy of Medicine. Its purpose is the diffusion of scientific knowledge in selected chapters of anatomy, physiology, bacteriology, pathology, pharmacology, and physiological and pathological chemistry, by the means of public lectures by men who are workers in the subjects presented. Each lecture is intended to represent the state of modern knowledge concerning the topic treated, and at the same time will be adapted for presentation before an audience consisting of that portion of the general medical profession who are interested in the scientific side of medicine. It is hoped that through these lectures the common interests of research workers and the medical profession may be profitably cultivated. The fulfillment of the purpose of the society has been entrusted to the hands of the following committee: Graham Lusk, *President;* Simon Flexner, *Vice-President;* George B. Wallace, *Secretary;* Frederic S. Lee, *Treasurer;* and Christian A. Herter, S. J. Meltzer, and E. K. Dunham. The membership of the society will consist of two classes, active and associate members. Active members will be laboratory workers in the medical sciences residing in New York. Associate members will be such persons as may be in sympathy with the objects of the society and reside in New York. The first course of lectures will be given on Saturday evenings during the winter of 1905-6 at the Academy of Medicine.

A Dinner in Honor of Dr. Emmet.—A dinner was given at Delmonico's on Monday evening of this week in honor of Dr. Thomas Addis Emmet on the occasion of his seventy-seventh birthday. About 125 of his medical friends were present. Dr. Emmet was escorted to the dinner by Archbishop Farley, who pronounced the blessing and also made a brief speech. Dr. E. C. Dudley of Chicago made the address of introduction. Others who spoke were Dr. W. M. Polk, Dr. W. H. Baker of Boston, Dr. S. C. Gordon of Portland, Me., Dr. George T. Harrison, and Dr. F. J. Quinlan.

Dinner Given to Dr. Barker.—Dr. L. F. Barker, who was formerly head of the Department of Anatomy at the University of Chicago, and who goes to the Johns Hopkins University as Professor of Medicine, was given a farewell dinner by the faculty of the University of Chicago, May 27. Toasts were responded to by Drs. Frank Billings, Hugh T. Patrick, and others.

Chicago's Mortality.—During the week ended May 20, there was one solitary death from typhoid fever in Chicago, in a population of nearly two millions—a fact worthy of record. Pneumonia is still struggling for leadership—70 deaths reported during the week, as compared with 58 from consumption. There have, however, been 703 fewer pneumonia deaths this season than last, while there have been 97 more from consumption. The ratio of pneumonia deaths to deaths from all cases is 13 per cent. less, and of consumption 17 per cent. higher than last season. A study of Chicago's decreasing mortality during the last ten years, as compared with the immediately preceding decade, corroborates the assertion that the most striking decreases are among diseases over which sanitary administration and preventive medicine have greatest and most direct control.

A Lowered Death Rate for New York City.—According to the figures of the Department of Health,

the death rate for last week was 17.11 per thousand. The rate for the corresponding week in 1904 was 20.62. The lowest death rate for one year that has ever been reached since the records have been kept by the Board of Health was 18.18 per thousand in 1893. If the present decreased rate continues, it is hoped to equal or better this record for the present year.

Plague in India.—The plague epidemic in India is continuing with unabated violence. For the week ending April 22 the mortality was nearly 55,000, or about 3,000 more than the figures for the preceding week. The mortality in the present year promises to exceed the records which stand as follows: Total deaths for 1901, 273,679; 1902, 577,427; 1903, 851,263; 1904, 1,022,299; and 1905, up to April 22, 630,968. It is doubtful if the figures tell the whole truth, and detailed figures show that the disease has spread throughout the country.

Yellow Fever on the Isthmus.—The latest reports indicate that the authorities at Panama have succeeded in getting the yellow fever situation well under control. A despatch from Col. W. C. Gorgas, received at Washington on May 24, stated that the last case had appeared on May 12, and that at the time of writing there was none on the Isthmus.

The Germ of Cerebrospinal Meningitis.—We do not often borrow items of scientific interest from the secular press, for we usually find just as good in the medical journals, but the following special despatch to the *Minneapolis Tribune* of May 14 is of such importance that we cannot refuse it space. The correspondent of the journal mentioned telegraphs from Rhinelander, Wis., that a physician of the place has startled the scientific world by isolating the bacilli of cerebrospinal meningitis. "Dr. W. E. Jurdan, of this city," as the correspondent announces, "has now on exhibition in his microscopical laboratory (in the blood serum), in a test-tube, a culture of this most dreaded of all bacilli. Before a meeting of some of the leading physicians of the State yesterday the doctor exhibited under a most powerful lens, assisted by a large piece of radium, a full-grown specimen of this terrible germ. It was given out after the lecture that the germ is very similar to the trichina found in pork, and does its deadly work on similar lines, except that it attacks only the spinal cord. The germ is provided with two knife-like horns and bores with a sort of gyrating motion through the vertebra until it reaches the spinal marrow. Full particulars of the discovery will be cabled to Paris and Berlin, as the doctor has had much correspondence with the French and German scientists on the subject. The doctor is very reticent and modest concerning his great discovery."

Opposition to the City Tuberculosis Sanatorium.—The residents of the town of Bloomingburg, Sullivan County, are up in arms against the establishment there of a sanatorium for the tuberculous of New York City. At a recent hearing before the Bloomingburg town board, Drs. Darlington and Biggs spoke in favor of the project, and many residents against it. The board reserved decision.

A Physician's Claim for Services Reduced.—The Probate Court in Chicago recently denied a claim of $100,000 made by a physician against the estate of one of his former patients. The Court declared that the physician took advantage of the close relation that existed between him and his late patient, and that any agreement which she made to give him $100,000 was void. Such an agreement, if there was any, the court held, was gained in violation of the confidential relation. By the Court's decree the physician got only $10,000.

A Special Train to Portland.—A party of physicians and their families who will attend the meeting of the American Medical Association, has been organized by Dr. Wiggin of this city. The excursionists will leave New York and Philadelphia on June 24, in a special train, including dining car, which will be retained during the entire trip. The party will visit the Yellowstone Park and other places of interest on the way west and will return via California, arriving in New York probably on the morning of August 3. The party will be limited to 125 persons. The party, so far as at present constituted, is composed chiefly of residents of New York, New Jersey, Pennsylvania, and the New England States. Those wishing to join the excursion are requested to communicate with Dr. Frederick Holme Wiggin, 55 West 36th Street, New York City.

Dr. John B. Murphy has accepted the Professorship of Surgery at Rush Medical College, having resigned his position as Professor of Surgery and Clinical Surgery at the Northwestern University Medical School.

Proposed City Hospital for Consumptives.—Specications for a new tuberculosis hospital on North Brother Island are now being drawn, and an appropriation has already been made by the city for its construction. The estimated cost is about $110,000. It will be used for the reception of cases in the early stages of the disease. The building will be about 114 feet long by 70 wide, and three stories in height. On the first floor will be the administration offices in the center, on each end being two large wards, 68 by 26 feet. The second floor will contain two similar wards at the ends, the central portion being occupied by toilets, storerooms, etc. On the third and top floor. The solarium floor will have two porches, one the sides of which can be opened, permitting the patients to be virtually out of doors. The central portion of this floor contains the kitchens and dining rooms. On the first and second floor will be four large porches, one on each side of the building on each floor. The solarium floor will have two porches, one at each end. There are already about seventy consumptive patients at Riverside Hospital, and the new hospital will accommodate at least eighty more. It will stand at the southwest corner of the island.

A Pure Milk Bill.—Governor Higgins of this State has signed a bill amending the agricultural law which requires owners or operators of milk stations for the sale of milk or the shipping of milk to cities to procure licenses from the State Commissioner of Agriculture. The applicant must file an affidavit declaring that he will not participate in or permit adulteration of milk at his station.

Dr. Samuel W. Bandler of this city has been appointed adjunct professor of gynecology in the Post-Graduate Medical School and Hospital.

The Maine Medical Association will hold its fifty-third annual meeting in Portland on Wednesday, Thursday, and Friday, June 7, 8, and 9, under the presidency of Dr. F. L. Dixon of Lewiston. The corresponding secretary is Dr. A. H. Sturtevant of Augusta.

The Ohio State Medical Association, at its annual meeting in Columbus last month, elected the following officers: *President,* Dr. Thomas C. Martin of Cleveland; *First Vice-President,* Dr. B. H. Dean of Lebanon; *Second Vice-President,* Dr. W. B. Hedges of Delaware; *Third Vice-President,* Dr. John A. Dickson of Ahstabula County; *Fourth Vice-President,* Dr. D. R. Silver of Sidney. The next annual meeting will be held in Canton in June, 1906. A resolution was passed that all papers read at an an-

nual meeting should become the exclusive property of the Association.

The Bronx Valley Sewer.—Governor Higgins has signed the bill creating a commission of one member each from Yonkers, Mount Vernon, and White Plains to provide for the construction of a $2,000,000 trunk sewer through the Bronx Valley, emptying into the Hudson, to prevent the pollution of the streams of Westchester County. The sewer is to be seventeen miles long, and will be the largest public improvement ever attempted in Westchester County. It will drain the entire territory from White Plains to Mount Vernon, including the Seventh Ward of Yonkers, and then, passing under the city of Yonkers by means of a tunnel, have its outlet in the Hudson River at the lower boundary line of the city of Yonkers.

Cincinnati Academy of Medicine.—At a meeting held May 15 a paper was read by Dr. William Gillespie, entitled "Maternal Diet with the Object of Lessening Bony Development in the Fetus." The writer did not think that a restricted maternal diet could materially affect the fetus, and even if it did he condemned the practice, giving it as his opinion that it was at least partly due to the poor bony development that premature labors were so difficult.

A Painting of Four of the Johns Hopkins Medical Faculty.—It is stated that Drs. Welch, Halstead, Kelly, and Osler will meet in London toward the end of this month, and will sit for a group portrait to be painted by Mr. John S. Sargent. The idea originated with Miss Mary E. Garrett of Baltimore, who will bear the expense of the painting.

Smallpox in Illinois.—An outbreak of smallpox has been reported at Arcola, Illinois, and an inspector of the State Board of Health has been sent there to see that proper precautions are taken to prevent the spread of the disease.

Chicago Pediatric Society.—At the annual meeting of this society held May 23, the following officers were elected for the ensuing year: *President,* Dr. Samuel J. Walker, reelected; *Vice-President,* Dr. Frank S. Churchill; *Secretary-Treasurer,* Dr. Emma Moore; *Trustee* for three years, Dr. I. A. Abt, reelected.

Illinois State Medical Society.—At the closing session of the fifty-fifth annual meeting of this society, Springfield was selected as the next place of meeting. The following officers were elected for the ensuing year: *President,* Dr. H. C. Mitchell, Carbondale; *First Vice-President,* Dr. W. K. Newcomb, Champaign; *Second Vice-President,* Dr. W. M. Marcy, Peoria; *Secretary,* Dr. E. W. Weiss, Ottawa; *Treasurer,* Dr. E. J. Brown, Decatur.

New Hampshire Medical Society.—The one hundred and fourteenth annual meeting of this society was held in Concord, and the following officers were elected: *President,* Dr. Ferdinand A. Stillings of Concord; *Vice-President,* Dr. Ira J. Prouty of Keene; *Treasurer,* Dr. D. M. Currier of Newport; *Secretary,* Dr. Granville P. Conn of Concord; *Assistant Secretary,* Dr. Loren A. Sanders of Concord.

Dartmouth Medical Alumni.—At the annual meeting of this association, recently held, the following officers were elected: *President,* Dr. Ezra Mitchell of Lancaster; *Vice-Presidents,* Drs. W. A. McGrath of Loudon and R. V. Baketel of Manchester; *Secretary and Treasurer,* Dr. H. N. Kingsford of Hanover.

The New Hampshire Association of Military Surgeons recently held its annual meeting in Concord and elected officers as follows: *President,* Dr. Ezra Mitchell of Lancaster; *Vice-President,* Dr. George Cook of Concord; *Secretary,* Dr. G. P. Conn of Concord; *Treasurer,* Dr. F. A. Stillings of Concord.

An Edict Against Beards.—It is reported that at the investigation of its secretary, Dr. J. F. Kennedy of Des Moines, the Iowa State Board of Health has requested physicians of that State to refrain from the wearing of beards on account of the possibility for the dissemination of infection otherwise afforded.

Marshall Hall Prize Awarded.—This prize, given by the Royal Medical Society every five years for the most brilliant discovery in connection with the nervous system, has been awarded to Dr. Henry Head, Fellow of the Society, and physician to the London Hospital. In the course of his studies on the nature of the sensory impulse, Dr. Head had some of the nerves of his own arm divided and made observations during the period of regeneration. The information obtained is embodied in an address recently delivered by Dr. Head, and is said to mark a very distinct advance in our knowledge of the sensory nerves.

Mosquito Extermination.—The New York Health Department has taken up in earnest the work of exterminating the mosquitos on Staten Island (Richmond Borough). Dr. A. H. Doty has been appointed to direct the work, and $10,000 have been appropriated for the purpose by the Board of Estimate.

Suggested Improvements in the Care of the Insane.—In the twelfth annual report of the New York State Charities Aid Association a number of important changes are urged upon the authorities. Among these are a plan for boarding out the harmless insane, improvements in the present unsatisfactory methods of deporting the alien insane, the employment of a dietist at every hospital for the insane, the early construction of the proposed reception hospital in New York and the construction of a new hospital between New York and Poughkeepsie.

Alpha Omega Alpha Society Banquet.—The annual meeting of this honorary medical organization was held at the Great Northern Hotel, Chicago, May 26. Prof. William E. Quine, Dean of the College of Physicians and Surgeons, made the principal speech, choosing as his title, "The Ideals and Practices of the Medical Profession." Other speakers were: Profs. W. S. Hall, Bayard Holmes, and S. W. Williston. The toastmaster was Prof. Joseph B. De Lee.

Obituary Notes.—Dr. Henry P. Stearns of Hartford, Conn., died on May 27 at the age of seventy-seven years. He was a graduate of the Yale Medical School in 1855, and was the first surgeon commissioned for a volunteer regiment in the Civil War. He was on General Grant's staff, and became a lieutenant-colonel. He was for many years superintendent of the Hartford Retreat for the Insane.

Dr. David G. Proctor of Thompson, Ohio, died May 15, at the age of seventy-seven years. He was born in the same village in which he died, and was graduated in medicine from the Jefferson Medical College in 1855.

Dr. John Smithwick of Sharon, Mass., died May 21. He was born in Boston and was graduated from the Albany Medical College in the class of 1869.

Dr. Henricus Wallace Westlake of Los Angeles, Cal., died May 15 of abscess of the lung. He was born in Canada and was a graduate of the University of the Victoria College, Cobourg (now affiliated with Toronto University) in 1887. Soon after graduation he removed to Los Angeles.

Dr. Henry Briggs of Grand Junction, Tenn., died May 16, at the age of eighty years. He was a gradu-

ate of the Memphis Medical College in the class of 1849.

Dr. William M. Line of Aberdeen, S. D., died suddenly on May 10, at the age of eighty-two years. He was a graduate of the Jefferson Medical College in the class of 1851, and had practised at Aberdeen for seventeen years.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

TROPICAL MEDICINE: MR. CHAMBERLAIN AT THE BANQUET—GYNECOLOGICAL SOCIETY'S DEBATE ON SURGERY OF CANCER OF THE UTERUS—ANTIVIVOS AGAIN—A PROPOSAL TO GOVERN NURSES—EXTRAVAGANCE OF THE COUNTY COUNCIL—ITEMS.

London, May 17, 1905.

Tropical medicine received another powerful impulse on Wednesday from Mr. Joseph Chamberlain, who presided at a festival banquet on behalf of the London school which, as you know, owes its origin to him. Since its opening five years ago 500 doctors have been equipped for work in the tropics by a course of study in it. More money is needed and the committee ask for £1,000 to repay debt, make further provision for the teaching staff, and subsidize research. Liverpool has set an example to the metropolis in this, and in the course of a telling speech Mr. Chamberlain asked, why cannot London emulate a provincial city? He had no jealousy in the matter and he wished that in every institution like this they could have a man as energetic as Sir Alfred Jones. He also paid a special tribute to Sir P. Manson and Major Ronald Ross. Sir R. Moore announced subscriptions amounting to over £9,000, and I hear that in the two days that have since elapsed the amount has been carried beyond £10,000.

The Gynecological Society invited Prof. C. Jacobs of Brussels to come and state his views on surgical intervention in cancer of the uterus. The professor accepted and read a paper at the April meeting, first thanking the society for electing him into their membership and promising to promote scientific relations between the British and Belgian Gynecological Societies. He said there were two essential objects in surgical treatment, viz., total removal of the infected organs and of the neighboring lymphatic territory. Operations must be as wide as possible from the site of infection, and the sooner undertaken the less the chance of extension. Early diagnosis and prompt action afforded the best chance. In 13 cases of supravaginal amputation 12 recurred within a year, the other one 15 months later. In 81 cases of vaginal hysterectomy there was an immediate mortality of 1.2 per cent.; four years later not one of the patients was alive. In 95 cases of abdominal hysterectomy his immediate mortality was 6.3 per cent., and recurrence took place in all the others within six years. In both varieties of cancer of the cervix infection took place through the lymphatics, therefore all glands of the parametrium and cellular tissue must be removed; glands were invaded beyond the limits visible to the naked eye, and the invasion of tissues far from the primary growth could be demonstrated. He would say cancer did not recur but continued; it would not reappear if completely removed. Actual results seemed to show that either cure is impossible or that operations are not perfect. Cancer of the cervix being primarily a local infection propagated by lymphatics, he advocated abdominal hysterectomy. Prof. Jacobs reported five inoperable cases which after injections of Doyen's serum improved enough to permit of surgical intervention.

Professor Taylor said the point which seemed to him forcibly brought out by Prof. Jacobs was the considerable distance from the point of invasion at which deposits were found. Surgeons were all agreed that early operations were decidedly best. As experience grew, he thought all operations for cancer less satisfactory than they ought to be. Whether the extended proceeding proposed would be an advance had yet to be proved.

Mr. Bowernan Jesset contributed some accounts of his experience, which extended to 180 cases removed by the vaginal method (which he preferred) except two or three of the combined operation. When the sacral or lumbar glands were involved, the method was of minor import.

Miss Anderson, M.D., thought it interesting to hear that Prof. Jacobs preferred the abdominal to the vaginal route, although the latter was so generally selected at the present time.

Dr. Lawrie hoped to hear more about Doyen's serum.

Dr. G. Elder attributed the results of Prof. Jacobs to operative dexterity, as few others had such a low mortality from the abdominal operation. Patients subjected to the vaginal operation recovered more evenly and had less shock.

Dr. T. Wilson thought the results of these extensive abdominal operations no better than those of the vaginal method. In cervical cancer one got 25 to 30 per cent. of cures after five years in cases operated on early enough.

Dr. F. J. McCann opposed these extensive operations. They were not analogous to those on the breast, as in them one could remove glands and intervening tissues. But in the uterus the proximity of the bladder, rectum, and ureters would limit extension. In cervix cases the vaginal was the preferable route because extensive local removal could be better done by it. For some time he had removed considerable portions of the anterior and posterior walls with the cervix. In cancer of the body of the uterus, if not too large, the vaginal route could be adopted; otherwise the abdominal might be tried. Some held that the glands were nearly always affected, but if so we should hardly get the results we do.

Dr. Helme preferred the experience of Prof. Jacobs to statistics and thought it was common sense that the wider the operation the better the patient's chance.

Dr. Arthur Giles thought English opinion at present unfavorable to extensive operations. So far recurrences did not seem less frequent, and Prof. Jacobs' statement as to the early involvement of glands might fill them with doubt as to the possibility of complete operations.

Dr. C. Martin was by no means tempted to go in for the extensive plan, as the results shown that evening were as bad as the older method.

Miss Blake mentioned that she had removed one to two inches of tissue with the cervix, but the cases were too recent to report.

Dr. Macnaughton Jones thought Prof. Jacobs had demonstrated the certainty of lymphatic invasion and the difficulty of assigning limits to it. He had had to make 700 sections of a gland from one of his cases before demonstrating its carcinomatous nature. Five or six years must elapse before speaking of cure.

Prof. Jacobs in reply referred to the difference in results of abdominal hysterectomies for fibroids, twenty years ago and now, as an encouragement to abandon the vaginal operation for the one he had described.

The anti-vivisectionists held their annual meeting on Wednesday. Of course, Mr. Stephen Coleridge was in full force and told his audience that "the vivisector who inflicted agonies untold on the animal was committing a wicked act no matter what lofty motives he professed." He then attempted to show by statistics culled from the registration returns that some diseases had increased of late years and therefore "the best thing for the human race was for the vivisector to let us alone."

Lord Llangattock occupied the chair, supported by a Bishop, an Earl, and some ladies and clergymen. His lordship declared his unfaltering faith that to torture animals was immoral and the most lofty motives could not justify immoral acts. He offered no explanation of his own conduct, though he has been publicly accused of torturing his pheasants, leaving scores of them wounded, to die in agony after every battue.

Strong opposition has been organized to a proposal to incorporate under the limited liability acts a trading society for education and registering nurses. It seems a cool proposal for a stock exchange venture to ask for registration to be committed to it. A deputation to the Board of Trade was received on the 5th inst., when Sir Victor Horsley, Dr. Langley Browne, Dr. J. H. Galton, Sir J. Crichton-Browne, Dr. Swanzy, Vice-President, R.C.S.I., and others spoke on the matter and showed that there was no objection to registration itself, but on the monstrous suggestion to entrust it to a lay body of traders. The education, training, and registration of nurses was a matter first of all for the medical profession, and if any others were consulted it should be nurses themselves. The general medical council had not been consulted, nor had the hospitals or licensing bodies.

The unbridled extravagance of the London County Council has placed such heavy burdens on ratepayers that they are awakening from their apathy and watching with deep interest the revolt against the education rate started at East Ham. The county council has incurred a debt on London which would suffice a small kingdom. It is now wanting to spend some three to four millions on more tramways, though those it has acquired have not proved profitable and may perhaps be superseded by motor-omnibuses. Further, the council wants to spend about £2,000,000 on building a fine county hall for its meetings and staff accommodation. The party which has the upper hand in the council seems to be without conscience in piling up the debt. Another scheme it has is to establish a series of receiving houses for pauper lunatics. The scheme is uncalled for, as the work it proposes to do is being done—and well done. Why, then, incur another million in building these receiving houses? This is worse than useless, for, as Dr. Toogood has pointed out, it will inflict an injury on the temporarily insane by branding them as lunatics, whereas, under the

present plan, they are only regarded as patients going to the infirmary for a time. The council's scheme would revolutionize previous lunacy legislation, the essential point of which is that the authority which first receives and certifies should not be the same as that which has the power of indefinite detention. Thus the council would abolish the safeguard of the poor lunatic, to extend its own grandiose schemes of building and controlling. There is, however, some hope that parliament will at length refuse to entertain the proposals for additional powers which the council is continually demanding, for the legislature is beginning to recognize that in establishing this body it has gone far to raise up a rival to its own authority. It is perhaps well that at this moment the education committee of the council has roused the ratepayers by a proposal to pull down and rebuild in a more costly manner nearly one hundred elementary schools, most of which are in very serviceable condition.

The British doctors who have gone to France to visit their French confrères are being received with every attention and profuse hospitality.

A question in Parliament suggests that laymen might sit on the General Medical Council. Does some layman aspire to such distinction or possess an axe in need of grinding?

The question of fixity of tenure for medical officers of health has been taken up by some of the best newspapers, so that perhaps Dr. Bond's case may be of service to his brethren.

OUR PARIS LETTER.

(From Our Special Correspondent.)

PROPOSED VISIT OF ENGLISH PHYSICIANS—INTERNATIONAL CONGRESS OF TUBERCULOSIS—GELATIN IN ANEURYSM—SYPHILIS AND GENERAL PARALYSIS—TREATMENT OF PROLAPSE OF THE UTERUS—SCOPOLAMINE ANESTHESIA—CALCULOUS ANURIA—LOCAL ACTION OF ANTIDIPHTHERITIC SERUM—PHLEGMATIA ALBA DOLENS OF FOUR EXTREMITIES—SURGICAL OPERATIONS ON THE INSANE.

PARIS, April 30, 1905.

THERE is much interest displayed in the reception to be held for the English physicians in Paris, and every day new names are added to the list of the entertainment committee. The list of guests includes a large number of physicians and surgeons from London and other parts of England, as well as from Scotland and Ireland. There are already 152 names, representing the élite of the English medical profession. The programme is arranged. Twenty-six women will accompany the visitors. They will be received by a committee of French women appointed for this purpose. The reception will begin on Wednesday, May 10, and will be concluded on May 13. It promises to be a most brilliant affair. On Wednesday evening the English physicians will be received at the Sorbonne by the Rector of the University of Paris and by M. Casimir-Périer, president of the Association of "Amis de l'Université." On Thursday afternoon the visitors will be received at the Faculté. From there they will go to the Assistance Publique and to the Hôtel de Ville. In the evening they are invited to dine by MM. Bouchard and Lucas-Championnière. The dinner will be followed by a reception at the home of Professor Bouchard. On Friday afternoon there will be an excursion to Chantilly, with lunch. In the evening the guests will be entertained at the Automobile Club with music and other forms of entertainment. The most celebrated artists will participate at this time. The last day will be marked by a visit to the Pasteur Institute. In the evening there will be a farewell banquet at the Grand Hotel, to which the English ambassador will have a special invitation. The guests will visit the hospitals in groups, choosing the special ones in which they are interested.

The Official Journal has recently passed a law offering to the minister of the interior the extraordinary credit of 100,000 francs for the aid of the International Congress of Tuberculosis, which will convene in Paris from October 2 to 7, 1905, at the Grand-Palais on the Champs-Elysées, under the distinguished patronage of M. Loubet, president of the French Republic, and under the honorary presidency of MM. Casimir-Périer and Léon Bourgeois, under the effective presidency of Dr. Hérard of the Academy of Medicine. The congress is divided into four sections and has formed 25 regional committees. Thirty-three foreign nations have organized their national committees, and they are all now working for the success of the congress. A great deal of remarkable scientific work is being done in the first three sections in relation to tuberculosis considered as a social disease. The committee of organization believes that it can now count on a reception for the congress by the president of the Republic, a reception at the Hôtel de Ville by the Municipality of Paris, a soirée by the president of the congress, a reception under the presidency of M. Loubet, at the opening of the Grand-Palais, a farewell reception in the large amphitheater of the Sorbonne, a banquet and a soirée. There will be trips in groups by special trains to the principal French institutions: the sanatoriums, marine hospitals, and so on. There will be organized at the Grand-Palais a scientific museum, which will remain open to the public during the entire month of October. The Tuberculosis Exposition will comprise four sections: Scientific (Museum), social, historical, and industrial.

Professor Dentu presented at the Academy of Medicine an account of a patient afflicted with a traumatic aneurysm of the tibioperoneal trunk, or the posterior tibial at its origin, which was cured after seven subcutaneous injections of a 2 per cent. gelatinized serum, given in a dose of 200 c.c. at each injection.

Professor Joffroy took up again the much-discussed question of the relations between syphilis and general paralysis. He declared at the Academy of Medicine that syphilis is one malady and that general paralysis is another; the latter can have its origin in syphilis, but it does not always depend upon syphilis. In the experience of Krafft-Ebing, in which he tried without success to inoculate general paralytics with syphilis, there was lacking the demonstration of the virulence of the material used, for healthy subjects. Joffroy declared that he was convinced that specific medication was of no more value in general paralysis from the prophylactic point of view than from the curative point of view.

M. Raymond, in resuming the discussion of this interesting subject, declared that the preponderating influence of syphilis as a factor, direct or indirect, of general paralysis, was well shown in the discussion called forth by the communication of Professor Fournier. Excepting M. Lancereaux, all of the speakers have agreed that syphilis dominates the etiology of this affection, and among all of the forms of diffuse meningo-encephalitis, that due to this malady takes the first rank.

At the Surgical Society, M. Chaput demonstrated the immediate perfect results which anterior myorrhaphy of the levators of the anus had given him in the treatment of genital prolapse in the woman, according to the proceeding of Groves (1905), completed by the posterior suture of Pierre Delbet.

Professor Terrier presented an interesting observation showing the benefits obtained in urinary surgery by the employment of scopolamine for general anesthesia. In a patient suffering from unilateral pyelonephritis with very sensitive bladder, vain efforts had been made to determine the condition of the opposite kidney by practising endovesical separation of the urine. But no separator could be endured, so extreme was the pain caused by it in the bladder. Anesthesia was then induced by scopolamine and the separator of Luys was then easily introduced without pain and left in place for as long a time as was necessary to establish a clear diagnosis.

Apropos of pulsatile arterial tumors in the parotid region, M. Tuffier reported a case in which the tumor, inextirpable on account of its close connections with the facial nerve, had been treated by electropuncture. M. Tuffier reported, besides, an observation on calculous anuria in one kidney. This report was presented to the society by M. Guibal of Beziers. Nephrotomy was performed and the cure was complete. An interesting point about the case was the ascites and hydrothorax observed in the patient. M. Tuffier thinks that it was a case of anuria by retention, the calculi in the ureter having been pushed into the bladder at the time of catheterization of the ureter, which was done at the time of operation by M. Guibal.

At the Hospitals Medical Society, M. Dopter insisted on the fact that antidiphtheritic serum has a local action. He has employed Martin's pastilles, which are composed of antimicrobic antidiphtheritic serum in compressed form, in 72 patients suffering from diphtheritic angina, in order to hasten the disappearance of Löffler's bacilli from the throats of these patients. The bacilli disappeared. There were no recurrences. At another meeting this society gave its attention to the treatment of pernicious anemia by medullary opotherapy. In one case only has the result been favorable. This was a case of the pernicious type, with marked myeloid reaction.

At the Society of Obstetrics, Gynecology, and Pediatrics, M. Pinard, at the meeting of April 10, reported, with all of the details, an interesting case of phlegmatia alba dolens of the four extremities, followed by multiple arthritis, in a woman 35 years old, III-para. This septicemia began on the thirty-first day and terminated on the sixty-third day. M. Pinard thought that the infection was due to too many and too tardy intrauterine interventions.

The Society of Ophthalmology, at its April meeting, received a communication from M. Chaillous on a case of traumatic infection of the eye, due to an anaërobic micro-

organism (*Bacillus perfringens*). M. Valude made a report on the work of M. Soderlinh relative to a case of grippal tenonitis followed by atrophy of the optic nerve.

The Society of Legal Medicine, at its meeting on April 10, discussed and voted on the conclusions of M. Picqué concerning surgical intervention in the case of the insane. It was agreed to discriminate between those who have lucid intervals and those who do not. The first class have the right to accept or to refuse intervention. Consequently, the surgeon can operate on the strength of a medical certificate establishing a condition of lucidity of the patient and his consent to the operation. For the other class, the society expresses a wish that the new law so decree that the insane patient shall be protected in matters of health as he is in matters of property, which are put into the hands of judiciary power.

At the Therapeutic Society, M. Mirovitch has called attention to the influence of automobiling and cycling on vision. After dwelling upon the ocular troubles which are caused by the constant pressure of the air, which is due to the too great rapidity of travel, and the irritation caused by the dust, M. Mirovitch showed eyeglasses which were designed to avoid these inconveniences.

OUR LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

WORK OF THE ARMY MEDICAL CORPS—DISINFECTION OF SHIPS—THE EYESIGHT OF FILIPINOS—COMMISSIONER OF PUBLIC HEALTH—RETIREMENT OF MAJOR CARTER AND APPOINTMENT OF DR. HEISER—EXODUS OF ARMY SURGEONS.

MANILA, P. I., April 8, 1905.

THE April meeting of the Manila Medical Society was the last that will be held until after the termination of the hot season, which will be about July. Four papers were read at this last session. "The Work of the Army Medical Corps in the Philippine Islands," by Charles Richard, Major and Surgeon U. S. Army. The paper gave a brief account of the results that have been accomplished by the military. It showed that much of the work which is now being successfully done was started by the army medical men at the time the islands were under military rule.

The second paper, "Disinfection of Ships," by J. D. Long, Assistant Surgeon, Public Health and Marine Hospital Service, was a clear statement of how an infected ship is treated at the port of Manila. He stated that ships may be disinfected for a number of reasons: (1) Because they arrived from an infected port. (2) On account of the occurrence of a case of quarantinable disease aboard. (3) To maintain a standard of cleanliness and for the purpose of destroying vermin. Owing to the latter, the comfort of the traveling public, especially in tropical countries, is greatly increased. He dwelt upon the great importance of having the necessary sanitary measures taken at the port of departure, and whenever that is properly done much annoyance and delay can be obviated at the port of arrival. In practice, it has been found that only four disinfectants are required. Holds and other closed places are first fumigated with sulphur to destroy vermin, and then they are either treated with formaldehyde or washed down with bichloride solution. Decks are mechanically cleansed and then scrubbed with bichloride. All movable textiles are taken ashore to the quarantine station's steam chambers and exposed to steam under a pressure varying from 10 to 15 pounds for a period of at least twenty minutes. The chambers are so arranged that the air can be exhausted, by which method the steam penetrates much better. There is also provision made for drying the fabrics before they come from the chamber. The water tanks of the ship are disinfected with permanganate of potassium. The crew and passengers are bathed, a strong alkaline soap being used in the baths. While this operation is going on, their body clothing is passed through the steam chambers and is then returned to the owners almost by the time they have completed their bath. The author also laid particular stress upon an experienced officer having charge of the work, owing to the enormous damage that might be done to the machinery and equipment of the vessel or its cargo by making a wrong choice of a disinfectant, as, for instance, the use of sulphur in a hold containing tea, which would ruin it and thus cause a heavy loss. He also called attention to the fact that a ship could be disinfected at a modern quarantine station without any serious delay to the vessel and practically no damage to the cargo.

The third paper, "A Comparative Neurological Study of the Filipinos and Americans," by R. L. Richards, M.D., U. S. Army, was an account of the physical examinations made by him of the native scout recruits prior to their admission to the army. He stated that the Filipinos had an exceptionally acute distance vision and color perception. In the discussion which followed, one of the speakers stated that in the examination at the port of Manila, of more than a thousand natives, who were applicants for the position of master, mate, pilot, etc., more than 2 per cent. were found to be color blind, and it was the exception rather than the rule to find a native with a good 20/20 vision. From these two conflicting statements then it would appear that considerable more work is necessary before any conclusions can be reached on this question.

The fourth paper, "The Diagnosis of Plague in Rats," by W. B. Wherry, M.D., of the Government Laboratories, was read by title only. Dr. Wherry showed a number of photographs made from some of his preparations.

Major E. C. Carter, U. S. Army, who has been the Commissioner of Public Health during the past two years, has been relieved by the Surgeon-General of the Army from further duty in the Philippines and directed to proceed to Washington, D. C. His position here has been tendered to Dr. Victor G. Heiser of the U. S. Public Health and Marine Hospital service, who has been the chief quarantine officer for the Philippine Islands for the past two years. Major Carter has performed the trying duties of Commissioner of Public Health with much tact. He was particularly fortunate in his work among the natives. Somewhat over a year ago, in recognition of his services, he was appointed a member of a committee which traveled all over the Orient for the purpose of investigating the opium traffic, in order that it might make recommendations to the government from which suitable legislation could be framed to regulate the opium traffic in the Philippines. It will, perhaps, be remembered that Congress has recently passed an opium law which is to apply to the Philippines.

Dr. W. B. Wherry has resigned his position as bacteriologist at the Government Laboratories, and has returned to his former position with the Rush Medical College at Chicago. There will be an unusual exodus of medical men from the Philippines during the current month. No less than sixteen have been ordered to return on the April transport. Among them are from the Army Medical Service, Assistant Surgeons Boyer, Halloran, Hall, and Woodall.

Progress of Medical Science.

Boston Medical and Surgical Journal, May 25, 1905.

A Consideration of the Pelvic Articulations from an Anatomical, Pathological, and Clinical Standpoint.—The attention of J. E. Goldthwait and R. B. Osgood was called to this subject by the occurrence of the case of a woman who was greatly disabled by marked relaxation of the pelvic articulations following pregnancy. But scant mention is made of the condition in the textbooks on obstetrics and gynecology. The cases naturally fall into three groups, the first including the cases in which there is definite relaxation associated with pregnancy, representing an exaggeration of a normal physiological condition; the second the cases in which the relaxation is associated with menstruation, apparently representing also a physiological condition, apart from any pathological change with which we are at present familiar; and the third, the cases in which the leison is due to trauma, general weakness, or some definitely known pathological process. The authors discuss in full the anatomical peculiarities of the pelvic joints and the general etiology of the condition, illustrating their contentions with several excellent photographs. As to symptoms, abdominal mobility is naturally prominent, but this varies greatly as to its extent. There is more or less discomfort and disability. Probably the most common complaint of the patients is of backache, referred at times definitely to the sacroiliac articulations, but often simply to the sacral region. This is usually worse on lying upon the back or with any back-straining exercise or occupation carried to the point of fatigue. When lying upon the back, the flattening of the lumbar spine necessarily strains the sacroiliac ligaments and is evidently the cause of the backache. As this takes place only when the muscles are relaxed, it explains the pain developing during sleep, the patient often being wakened with the severe suffering. This is usually relieved by stretching or by some other change of position in which the lumbar spine and the sacrum are drawn up. The backache which develops when the patient is up and about may be brought on by any posture which causes strain on the sacral ligaments, such as lounging, sitting with the lumbar spine thrown back, or prolonged standing and walking. At times the backache is produced by a jar or by some sudden misstep, in which the muscles are taken off their guard. The treatment (which is described in detail) consists essentially of joint protection and replacement of any subluxated bones. This can be done by immobilization, bodily attitude, plaster jackets and various applications of webbing bandages, plaster strips, braces, etc.

New York Medical Journal, May 27, 1905.

The Surgical Paradox.—E. Van de Warker takes up again the subject of the dangers of curettage of the uterus,

replying to an article by Dr. D. H. Craig, in which some of the ideas of Dr. Van de Warker's previous paper on the subject were controverted. He regards accidents as less liable to occur in the hands of physicians who are good mechanics and began young. Older men find it difficult to educate into being special faculties. It is difficult for them to follow out the rules of rigid antisepsis. There is a great difference between being taught how to do a thing and being trained to do it. The dangers of puncture of the uterine walls are more real than is often admitted. There is a strange indifference on the part of the laity in their choice of operators. Many a surgeon who is clever in hysterectomies, ovariotomies, etc., is an unsafe operator in uterine curettage. Dr. Van de Warker believes that the statement that the vagina is sterilized by its own secretions rests on too narrow a margin of truth to serve as a justification for the lack of most rigid application of the principles of modern aseptic surgery. The danger of rupture or perforation of the uterine wall comes principally from the enormous force exerted by the leverage of the expanding blades of the dilator. Much of the bad surgery of the present day is, according to the author, referable to the text-books written on special surgery for the general practitioner. These books inspire middle-aged men to undertake surgical operations for which they are in no wise fitted, for they have not learned how to think and work under the rigid conditions of modern surgical science. The surgeon estimates a man's fitness as a surgeon by the number of his recoveries, but the public has another standard, which appears to be the number of his operations and his success in boasting of them. While we have been advancing the cause of medical education we have neglected to educate the people in discrimination and good medical and surgical judgment. Until we do this, the unfit and belated surgeon will do his share of work along with better men. Another unfortunate fact is that the colleges of the present day teach only surgical rudiments and not surgical art. Some men supplement their college work by a hospital experience; others go to the post-graduate institutions, but they have no basic knowledge of surgery by which to profit from what is taught. The author believes that post-graduate institutions should be under the control of the State regents —in fact, the same way as the under-graduate schools are.

Medical News, May 27, 1905.

The Widal Reaction.—E. Andrade has experimented with the Widal test in order to determine the value of the method and incidentally the relative value of living and dead cultures of the B. typhosus. His conclusions are as follows: (1) Living and dead cultures are about equally sensitive to the action of the agglutinins of typhoid fever, though in dead culture the reaction may require a longer time to take effect, and it is therefore necessary to keep the specimen under observation for two hours. In some cases the reaction is quicker with the dead than with the living cultures. (2) The dried blood method is equally effective with dead as with living cultures. (3) The reaction, when it takes place, is more characteristic with dead cultures than with living cultures. There are no pseudo-reactions with dead cultures. (4) Dead cultures do not seem to lose their sensibility to the agglutinins of typhoid fever for a long time. The author has now in use a dead culture which was prepared six months ago, and it reacts just as typically as when first used.

Two Unusual Cases of Gastric Cancer.—The cases are reported by W. F. Cheney. Case 1 was that of a man aged 54 years, in whom the common symptoms of cancer of the stomach were all lacking. He had a good appetite, ate heartily, digested well, had no nausea or vomiting. No gastric pain after eating, no emaciation, and no cachexia. A diagnosis had been made of malignant disease of the liver, but there was no reason to suppose that it was secondary to disease of the stomach. Autopsy, however, showed that at the fundus of the latter organ, about in the middle, between the cardiac orifice and the pylorus, at the greater curvature, there was found a circular ulcer about 5½ cm. in diameter, with elevated margins; the margin and the bottom of the ulcer were infiltrated with grayish white hard tumor masses. In the middle of the ulcer the stomach wall was perforated, the perforation measuring about one centimeter in diameter, and closed by a tumor mass in the ligamentum gastro-colicum. In the tail of the pancreas was found a tumor mass about the size of a walnut; and a considerable number of lymph glands in the upper retroperitoneal space were enlarged and infiltrated with tumor. Microscopical examination of the tissues showed that the process in the pancreas, lymph glands, fundus of the stomach and liver was carcinomatous. Case 2 was that of a man of 37 years; the diagnosis of gastric cancer was not suspected. Malignant disease was considered a probability an account of the emaciation, anemia, cachexia, and the presence of an abdominal mass. This was regarded as connected with the spleen, but on exploring the abdomen the tumor proved to be an enormous carcinoma of the splenic end of the stomach adherent to the anterior abdominal wall and associated with a perigastric abscess. Death occurred one week after operation.

American Medicine, May 27, 1905.

Chylous Ascites.—James F. Bell reports a case, in a man of 57, in which the amount of fluid withdrawn from October 1 to December 17 aggregated 106,370 c.c. There was little loss of strength or weight, the patient, at the last paracentesis, weighing but 5 pounds less than his normal average. The history would suggest a rupture of a large lymph duct, the thoracic duct, the receptaculum chyli, or a chylous cyst of the mesentery which has continued to discharge into the peritoneal cavity. The cause of the rupture is unaccounted for, and no growth or neoplasm can be found in the abdomen. Dr. S. P. Beebe discusses the literature on analysis of chyle and reports the results obtained from examination of the fluid in this case.

Some Results of Abdominal Operations.—George Erety Shoemaker deals with 100 unselected consecutive cases from his service at the Presbyterian Hospital, with five deaths, one moribund when admitted and rapidly incised for pus drainage without diagnosis, one seen two weeks after onset with gangrene of several feet of small intestine, two bad chronic pus cases, and one chronic inflammation of tubes, ovaries, and appendix. In the 95 recoveries hysterectomy was done 20 times; 9 for malignancy. In malignant cases the method preferred was the separation of the growth through the vagina, followed by removal of the uterus through a suprapubic incision. In the 12 cases of fibroid tumor the method preferred was hysterectomy by supravaginal amputation. Operation was done primarily for appendicitis 11 times, but in the course of other abdominal operations the appendix, not being normal, was removed in 22 other cases, so that altogether in one-third of the cases of the series the appendix was removed. The method preferred was by ligation and purse string burial of the stump. The removal of the appendix probably increases the risk of the primary operation to a very slight degree, and is not advised under unfavorable conditions, as in a complicated hysterectomy. Of the 6 cases of extra-uterine pregnancies all the patients recovered. A large number of other operations were done in a corresponding period, such as plastic perineal work, suspension of the kidney, curetting, etc., some of these operations being in combination with abdominal section and all without mortality. In 68 per cent. of the cases requiring perineal repair the anterior vaginal wall was also treated by the excision method.

Lobar Pneumonia in Children.—Marion McH. Hull directs attention to the greater frequency of this variety of pneumonia in children than is ordinarily supposed and the characteristics of the childhood type—its greater tendency to begin without a chill and to terminate by lysis; for resolution to be delayed and to be followed by abscess of the lung or empyemia; and the greater frequency of otitis as a complication on account of the anatomic peculiarities of the eustachian tube in children. Otitis has occurred in 50 per cent. of Dr. Hull's cases, in many without pain. Difficulty of early diagnosis is characteristic. The degree of leucocytosis may be of value in determining the prognosis.—

Journal of American Medical Association, May 27, 1905.

Infant Feeding.—F. S. Churchill discusses the embarrassments of infant feeding when breast milk is not available, and the unsatisfactory results of the common practice of diluting cow's milk with water in such cases. He summarizes practically as follows: Cases of difficult feeding in infancy are: (1) those of fat indigestion; (2) those of sugar indigestion; (3) those of proteid indigestion. Each of these may occur alone or in combination with the others. Proteid indigestion is most common, but fat indigestion is also frequent. Each must be treated individually, the form of indigestion present must be ascertained if possible, and appropriate measures be adopted. The treatment is almost exclusively dietary; the fats and sugar can be regulated by varying the amounts of cream and sugar in the food. The composition of cows' milk, with its high caseinogen and low lactalbumin content must be cut down or eliminated, if need be, and the lactalbumin retained. This twofold object is attained by feeding whey. Increase in quantity and quality of the food must be made gradually. In conclusion, he suggests the desirability of careful study of artificially fed infants and publication of the results.

Pyloric Stenosis in Infancy.—Charles M. Scudder reviews the literature of pyloric stenosis of infancy, and describes the symptoms, diagnosis and treatment. He recognizes two groups, the subacute or chronic, and the acute fulminating cases. While most cases are fairly typical, in some the differential diagnosis is difficult, and a careful study of each symptom and the sequence and grouping of symptoms should be made till the diagnosis is reached by

a process of exclusion. He has little faith in the medical treatment, and believes that the condition is practically hopeless without operation. The results of operations since 1898 show a saving of over 50 per cent. of the cases, of which probably all would have died if let alone. An analysis of the fatal cases shows that many of them were due to mistakes or errors of technique, too late operation, etc. The operation should be rapid, free from causes of shock, sepsis or hemorrhage, the parts to be handled gently and isolated outside of the abdominal cavity. The Loreta operation is condemned. Pylorectomy is too severe and pyloroplasty is not recommended save in exceptional cases. Some form of gastroenterostomy is best for most cases, but owing to the shortness of the infant mesentery and other reasons the anterior operation should be avoided if possible. The Finney operation of gastro-pyloro-duodenostomy may be suitable in some cases, or if not feasible, Köcher's gastroduodenostomy may be useful. After-care is of vital importance, and if possible an expert in feeding a baby should have charge. Absolute quiet is essential, and rectal feeding may be needed for a few days. Scudder does not discuss the etiology to any extent, but thinks that a congenital hyperplasia may occur and a spasmodic contraction of this, after birth, is frequent if not the rule.

Tolerance to Nitroglycerin.—According to D. D. Stewart, an excessive tolerance of nitroglycerin can be readily acquired if care is not taken to avoid a too rapid increase of the dose, hence the drug, though intelligently employed, is often of little service. The best rule for giving the drug for its effects on blood pressure, is, in his opinion, to administer it four times a day in dose just sufficient to produce the slightest feeling of fullness in the head or slightly to quicken the pulse. If more than this is given, an undesirable tolerance is likely to be established. When a rather rapid increase seems needed to keep up a constant effect, it is best to discontinue the drug for two or more days, at intervals, and to resume its use with a smaller initial dose. By so doing the use of very large doses and strong solutions, which are not exactly safe to handle, will be avoided. Nitroglycerin, he thinks, has not met expectations as a remedy in conditions of persistent high tension, and he now uses it in such cases less frequently than formerly, endeavoring at first, at least, to relieve by limiting the nitrogenous intake and maintaining free action of the skin and bowels. Aconite is often substituted for nitroglycerin in these cases with advantage.

Peritoneal Gauze Drainage.—W. D. Haggard calls attention to the fact that the fancied necessity for drainage after abdominal section has been greatly lessened by the knowledge that the peritoneum can easily dispose of considerable amounts of blood and serum and that accumulations of pus are generally sterile. He calls attention to the likelihood of wound infection from drainage after hernia operations, and to the danger of resulting hernia after infected abdominal wounds, and states that this is infrequent after wounds, which have healed aseptically. He advocates drainage through the cul-de-sac of Douglas, and describes his methods in detail. He places the gauze in the abdomen so that, after the operation is completed and the incision sutured, the gauze may be reached through a new incision in the vagina with less danger of infection.

Headache from Malaria.—C. J. Stedman reports a peculiar case of malaria, without temperature symptoms, occurring in the middle of an Arctic winter. The only symptom —headache—appeared each forenoon and lasted five or six hours. The patient acknowledged no previous malarial infection. The blood examination showed no perfect organisms, but numerous malarial spores, and these rapidly disappeared with the symptoms under quinine. He regrets that the blood examination was not made earlier and the exact character of the parasite determined, though the appearance indicated the tertian organism. The case is reported on account of the unusual circumstances and manifestations and as a suggestion of the importance of early blood examination.

The Lancet, May 20, 1905.

Epidemic Cerebrospinal Meningitis and Posterior Basic Meningitis.—According to O. Hildesheim, these two conditions are quite distinct, the one from the other. His views are based on an analysis of 100 cases of the latter malady. More than one-half the cases of posterior basic meningitis occur in infants under one year of age. The cases are more protracted, and most of their sequelæ are associated with internal hydrocephalus. Amaurosis without optic neuritis occurs in about one-third of all the cases, while optic neuritis is rare, though fairly common in the epidemic form. Deafness is uncommon in the posterior basic disease, but very frequent in the epidemic form. Skin lesions, though they occur, are much less common in the former than in the latter. The author believes that the ultimate decision as to differential diagnosis must rest with the bacteriologists. He adds that this problem is a difficult one, and that it is very important to realize that one has not necessarily found the cause of the disease because one has shown the presence of a potentially pathogenic organism in a case of meningitis. He had under his observation a case which the physician in charge considered an example of pneumococcus meningitis. He performed a lumbar puncture and the pathologist reported that he obtained a pure culture of pneumococcus. Nevertheless, the necropsy revealed a typical tuberculous meningitis.

Congenital Elevation of the Scapula.—C. R. Keyser reviews previously recorded cases and reports his personal experience with a girl of nine years without antecedent, personal or family history. On examination, the left scapula was found to be two and a half inches higher than the right, but the bone was of the same size as its fellow. Movement of the arm, both active and passive, was normal. There was no osseous bridge to be felt between the vertebral border of the scapula and the spine, nor was there any lateral curvature of the spine. The spinous process of the third dorsal vertebra, however, felt thicker than normal, and was apparently displaced slightly to the left. The interior angle of the scapula was on a level with the interval between the sixth and seventh dorsal spines. There was no paralysis of any muscle. The *x*-rays showed nothing abnormal, and the two arms were of the same length. The child's head was rickety in appearance, but there were no other signs of rickets or of any other deformity. The teeth were slightly notched and ridged, as is generally the case in ill-nourished children. As the child suffered absolutely no pain or inconvenience from her condition, no active treatment was adopted, especially as the deformity was barely visible, except when the patient was undressed.

Is Man Poltophagic or Psomophagic?—This question is discussed by H. Higgins. These words introduced by Gegenbauer, signify respectively the swallowing of finely and coarsely masticated food. The horse is a typical example of the first, and the dog of the second. The author describes minutely the structure and function of the parts concerned in swallowing in man, and describes some interesting experiments which cannot be detailed here. His general conclusion is that man is designed to be a poltophagic animal, and that if poltophagia were universally practiced, the daily quantity of food required to support life would be much less than the present more or less "bolting" habits of the average man have called for.

British Medical Journal, May 20, 1905.

Remarks on the Causes and Treatment of Edema.—J. Dixon Mann declares that edema, due to failure of cardiac or of renal compensation, or of the two conjointly, is a common clinical phenomenon, the pathology and treatment of which demands renewed consideration in the light of recent investigations on the subject. In simple cardiac edema the cause is essentially hydrodynamic in nature. The edema is chiefly due to changes in the vascular endothelium, caused by the imperfect supply of oxygen and of nutrient material to which the partial stagnation of the blood gives rise. The vascular walls become abnormally permeable and the resulting transudation is increased by the low pressure of the blood supply to the kidneys and the coincident retention in the tissues of sodium chloride. The edema in these cases is not the direct result of back pressure, or at least to a limited extent only. The edema due to kidney disease is not so easily explained. Some of the causes are, changes in the vascular endothelium due to the toxic action of waste materials in the blood, which are normally removed by the kidneys; the defective elimination of water by the kidneys, and probably the occurrence of hydremic plethora are influential factors. Recently, many experiments have been made in regard to the part played by sodium chloride in the development of edema. It is known that edema may increase without diminution in the daily volume of urine, or with such diminution as is insufficient to account for the quantity of water retained. The writer declares that while he hesitates to accept implicitly the theory that retention of sodium chloride is the exclusive cause of renal edema, he is satisfied that restriction of dietic salt in the edema of Bright's disease tends to promote its dispersion. As to the treatment of edema, when the heart alone is at fault, physiological rest is the most valuable of all remedial agents. In most cases of failure of cardiac compensation, rest alone is not sufficient to restore it. Digitalis, among medicinal remedies, is most valuable. It must be remembered, however, that few preparations vary so much in activity as does this one. Alcohol in certain cases is very helpful in tiding the heart over a critical period, but its effects need close observation. Diseased kidneys are generally a contraindication to its use. Renal incompetence is, as a rule, more difficult to treat than simple cardiac incompetence. The comparatively new class of diuretics which are purin derivatives have materially increased the efficiency of renal therapeutics. One of these is caffeine. When the kidneys fail to respond to the

stimulus of diuretics, the skin offers a route for the elimination of both water and solid urinary constituents. The hot-air bath and the vapor bath are efficient auxiliary means of reducing edema and at the same time of promoting the elimination of nitrogen and of salts, especially of sodium chloride. But during the bath the patient should not be allowed to drink copiously of water, as this neutralizes the remedial action of the bath. Cathartics avail little in the dispersion of edema. Of all foods, milk is the least harmful to the kidneys. Its exclusive use it not without objection, however. The ingestion of much liquid tends to increase the amount of water already retained in the system. A moderate amount of solid food is generally advisable. Generally, too, food stuffs which contain a high percentage of extractives should be eliminated. Proteids may be replaced by farinaceous dishes, cream, butter, bread, potatoes, and sweets, eggs, weak tea, and coffee. When there is an ample volume of urine, the intake of liquid usually needs no restriction; with scanty urine, the intake should be governed by the weight of the patient. When the weight increases, the intake should be restricted. The progress of the edema is ascertained by periodically weighing the patient.

Treatment of Seasickness.—J. Metcalfe Sharpe believes that seasickness is a nervous vomiting, and that the reflex action is transmitted by the vagi to the solar plexus. He has found that by paralyzing the accommodation of one eye, that is, by converting one eye into an "ametropic" and allowing the other to remain "emmetropic," the intensity of the symptoms is greatly ameliorated. His method of treatment is as follows: Two or three drops of a solution of atropine (4 gr. to the ounce) or other mydriatic are put into one eye daily; or one eye is merely bandaged. In this way the principal focus is altered and the motion of objects on board the ship, which doubtless forms the impulse, is not so uniformly transmitted to the brain. The results are excellent. Cases, more or less blind in one eye, that have been observed, have not experienced seasickness since blindness.

Camphor Poisoning.—Graham Grant describes the case of a man who was thought to be dying. While an emetic was being prepared, the patient vomited and seemed to get well immediately. He was taken to the hospital, whither he walked with no difficulty. A little later he was sized with a convulsion, which rapidly passed into collapse. The by-standers again thought that the man was dead. Within ten minutes, when the writer arrived, he found the patient standing. He smelled strongly of camphor, as did also the vomit. The pupils were dilated and the pulse was flabby, but there were no other symptoms.

Berliner klinische Wochenschrift, May 8, 1905.

Quinquaud's Sign.—Hoffmann and Marx discuss the nature of this phenomenon, which Fürbringer describes as follows: If the spread fingers of the patient are placed against the palm of the observer's hand, for the first two or three seconds nothing is noticed, but then faint shocks are felt, as if the bones of the hand were knocking against each other and against the observer's palm. According to the intensity of these movements there are produced all gradations, from a gentle rubbing to true creaking crepitation. The sign is supposed to be indicative of chronic alcoholism, though various observers have published different opinions as to its significance. The present authors tested it on 1,018 of the inmates of a detention prison, whom they divided into four classes, according to their abstinence, or degree of alcoholism. The conclusion is reached that the sign affords reliable information and has distinct value in making a diagnosis of alcoholism. The absence of the sign or its presence in moderate intensity does not give definite information either for or against abstinence, or the abuse of alcohol, but the probability in favor of the former is as three to two. A marked degree of the phenomenon, however, indicates excessive drinking with a probability of three to one. The sign has no connection with the ordinary tremor, as the authors in many cases saw the one without the other, and they believe that it is due to a longitudinal vibration of the bones instead of the transverse motion which causes the latter. The sign may also be detected by auscultation, as a sound is produced which is audible through the stethoscope. It is possible to stimulate it artificially by muscular fatigue or the use of the faradic current.

Münchener medizinische Wochenschrift, May 9, 1905.

The Treatment of Hay Fever.—Denker says that while Dunbar's theory of hay fever etiology has much to commend it, not all persons who are subject to the disease are susceptible to the effect of the poison isolated by Dunbar from pollen of the graminaceæ. The author obtained some of the preparation from Dunbar himself and tested its effect on three patients who for years had been sufferers from hay fever. The experiment was made during a period when the patients were free from trouble, but even when the toxin was applied undiluted to the conjunctiva or nasal mucosa no reaction was produced. The author considers that there was no doubt that the patients were really hay fever subjects, and there was no question as to the freshness of the toxin. The results obtained by the use of the antitoxin are, however, quite favorable. Lübbert and Prausnitz having reported 57 per cent. of successful cases, but the effect is very evanescent and the patients are required to sleep with closed windows. The author has developed a method which is free from these objections, as it prevents outbreaks in the following and even in the second year. It consists in massage of the nasal mucous membrane in order to reduce its abnormal sensibility. The entire mucosa, as far as it can be reached, is well anesthetized with a solution of cocain and adrenalin, and the inferior, middle, and if possible the superior turbinated bones are subjected to progressively more forcible friction with a cotton-wound probe. The septum is similarly treated. The treatment is carried out daily and at first takes two to three minutes, the time being lengthened gradually to three to four minutes for each nostril. Eight cases are reported in all of which this treatment was markedly effective, in some instances the attacks being put off for several years, while the acute stages of the disease were promptly relieved.

A New Form of Counting Chamber.—Bürker describes a new form of chamber for counting blood cells. He says that the old Thoma-Zeiss cell has the following disadvantages: It is difficult to adjust the cover glass properly, the cells are frequently irregularly scattered, variations in atmospheric pressure give rise to differences, and the ruled area comprises but a small portion of the entire surface. The first objection is met by the new apparatus inasmuch as the cover glass is put in position before the addition of the blood mixture, so that the operation may be carefully performed. There is no chance for unevenness of distribution of the cells, as the mixture enters the chamber almost instantaneously through capillary attraction. The chamber is open on two sides, so that changes in pressure have no effect, and the fourth difficulty is obviated either by not having any ruled area at all or by having this cover nine square millimeters. The former type is especially adapted for accurate work, and in this the area to be counted is marked off by the use of suitable diaphragms in the ocular, which are calibrated by means of stage micrometer accompanying the instrument. For ordinary use the other type, with large ruled area, is advised, and this yields more accurate results than the old form, even though only eighty squares be counted instead of two hundred.

The Possibility of Separating Different Albuminous Bodies Emanating from the Same Organism by Means of the Precipitin Reaction.—Forssner says that so far the results of experiments undertaken with this end in view have not been very encouraging, and he describes some tests of his own which gave positive results. Extracts of guinea pig liver, kidney, and spleen and serum were injected into rabbits and the adapted serum tested for precipitins with solutions of these four bodies, using the principle of partial saturation. The results led Forssner to conclude that it is possible to distinguish by this method solutions of guinea pig kidney, liver and serum and probably spleen also. On injecting liver extract into guinea pigs several partial precipitins are produced, some of which react with the serum kidney, and spleen extract as well as with liver extract; others are specific only for kidney and liver extracts, or for liver alone. The precipitins obtained by the injection of kidney extract show the same relative properties, a single body being present which is specific for kidney alone, and the spleen precipitins react most strongly with splenic extract. Some of the precipitins obtained with blood serum reacted also with the organic extracts, but the larger part were specific for the serum, and it is impossible to exclude the possibility that in the former instance the reaction was due to traces of blood serum in the organic extracts. The liver and spleen appear to have more properties in common than the liver and kidney or kidney and spleen.

Deutsche medizinische Wochenschrift, May 11, 1905.

Carcinoma.—König terminates an extensive article on this subject with the following conclusions: The nature of the disease is still unknown, but according to König's views it has a specific cause, which in all probability is parasitic in nature. The prevalence of carcinoma has not increased, at least there is no proof that it has, its apparently greater frequency being due to the more exact statistics and better diagnoses of modern times. König has never encountered groups of cases simulating epidemics, and he has seen nothing which leads him to believe that it can be transmitted from person to person. He has never known of a nurse acquiring the disease from a patient, and although the disease may be transplanted, he does not believe that it is transmissible by inoculation. There is a predisposition to carcinoma depending first on general grounds, such as ad-

vanced age, and a special predisposition due to heredity, which may be transmitted from father to children or by skipping a generation from grandfather to grandchildren. Nothing definite can be said regarding the frequency of this predisposition. In numerous cases trauma must be regarded as affording a predisposition to carcinoma, and the same is true of ulcers which are irritated and of increase in the functional activity of a gland, as of the breast. Primary carcinoma occurs only in epithelium, but it can develop in any position in which epithelium is found. For a time it is a purely local disease, but as its course cannot be predicted, it should be removed as soon as possible, preferably by radical operation, which cures 30 per cent. of the patients. Sometimes, however, recurrences take place years later, owing to the peculiar latency of the germ. Radiotherapy has cured small growths and improved large ones; if it is to be tried in place of operation, it should be in small superficial cancers or in those so advanced as to be inaccessible to the knife.

The Infection of Monkeys with Syphilis.—A. Neisser, who is now in Batavia continuing his studies on the susceptibility of monkeys to syphilitic virus, reports on the results of experiments made on 53 monkeys of the lower orders carried on at Breslau during the past winter. Twenty-five animals were inoculated by scarification of the skin about the eyebrows, the genitals, abdomen or breast, and in all but two positive results were obtained. The sores developed 20 to 35 days afterward and corresponded fairly closely to human chancres. Typical glandular swellings were not observed, and no general manifestations were produced in any case. Inoculations with primary lymphnodes were made in two cases, and were also effectual. Subcutaneous inoculations, however, with bits of chancre tissue and condylomata, as well as intraperitoneal and subcutaneous injections of undefibrinated syphilitic blood gave negative results. In a large number of instances cutaneous inoculations from one animal to another with the primary lesions produced from infection with human virus gave positive results. In discussing this feature of the experiments the author draws attention to Metschnikoff's claim of having produced reduction in virulence and immunity in this way. Neisser believes, however, that in these cases Metschnikoff's reinfections did not succeed, not because immunity had been produced, but because the animals had been made syphilitic in the attempt to render them refractory to infection. It is evident that syphilis produces less and less characteristic lesions in monkeys the further removed they are from man, and the author says that the next problem that experimenters must solve is to determine whether, and if so, where, in the body of the syphilitic animal, virulent material would serve to reinfect is to be found.

Experimental Observations on the Significance of Meat Extractives in Relation to Gastric Digestion.—Sasaki says that although it has been recognized that the extractives of meat exert a very pronounced stimulating effect on the nervous centers, the relationship to gastric secretion of the bodies of this nature taken into the stomach at the beginning of a meal in the form of the ordinary bouillon has not been duly recognized. He experimented with a dog, a portion of whose stomach had been isolated by the Pawlow operation. The animal was given, after a 24-hour fast, 100 c.c. of water, followed in half an hour by the same amount of milk, and the gastric secretion was then examined. The experiment was then repeated, using instead of distilled water an equal amount of 10 per cent. solution of meat extract, with the result that the gastric juice was greatly increased in amount and possessed a higher acidity. The secretion also continued for a much longer period of time than when water was used as an appetizer. The author therefore concludes that by giving meat extractives a short time before the main portion of the meal, the gastric mucous membrane is stimulated to produce a much more abundant and active digestive secretion than is otherwise the case.

French and Italian Journals.

The Pathogenic Action of Intestinal Worms.—Giuseppe Messineo discusses the action of intestinal worms in the intestine, whether their morbid action results from simple mechanical irritation, or whether the products of the worm's life is toxic to the individual. He has made injections into various animals of a solution extracted from the different varieties of worms, and observed the poisonous effects. He finds that not only a simple extract of tenia and ascoris causes the death of the animals receiving the injections, but also that a precipitate obtained from this solution by sulphate of ammonia, ascetic acid or phosphotungstic acid has a poisonous effect. The injection of the extracts causes a marked inflammation of the gastrointestinal tract, and the intestinal cells brought in contact with it in vitro are disintegrated by it. Subdural injection of the solution produces chromatolysis of the ganglion cells, and dilatation of the vessels of the entire nervous system. The first symptoms observed in all the animals were nervous symptoms, especially of the motor tract.—*Giornale Medico del Regio Esercito,* April 30, 1905.

The Blood in Osteomalacia.—Nicola Pende gives us the results of his observations of the blood of ten patients suffering from osteomalacia, who were treated at the Lateran Hospital at Rome. He took care that none of them should be pregnant or in the puerperal state, which would involve blood changes, and took cases that were in other respects normal. Some of the cases were in the early, some in an advanced stage, and one died while under treatment. All were treated with phosphorized cod-liver oil. The results of his blood examinations were as follows: The density of the blood was in general reduced; the alkalinity is not diminished, but usually normal, and in some cases increased; the resistance of the blood corpuscles to solution is increased; this is in part the expression of an irritative state of the medulla of the bones, which causes a larger number of erythrocytes to enter the circulation, in part to the pulmonary insufficiency of the deformed chest. Erythrocytes may or may not be diminished, due to hematopoietic irritation of the bone marrow, and to peripheric blood stasis; there is a certain increase of cosinophile leucocytes; the lymphocytes are diminished; there is a preponderance of large mononuclear leucocytes, especially in the transition stage of Ehrlich; myelocytes were found in only one case; the coagulating power of the blood and its cryoscopic point are not changed. All the patients were benefited by treatment, as was shown by improvement in the blood dyscrasia. —*Il Policlinico,* May, 1904.

Action of Radium Rays on Virus of Rabies in Vitro and in Animals.—Guido Tizzoni and Alessandro Bongiovanni have made experiments on rabbits as to the effects of the radium rays on the virus of rabies. He has used the fixed virus, which, by its high potency, represents the maximum experimental force of the virus. Two series of experiments were made, one in vitro, and one on animals. In vitro the radium rays quickly decompose the virus when maintained at a temperature of 12-15° C, and the virus loses its toxic power in a short time. When the rays were applied to animals as soon as the poison was injected, it had a marked effect, as well against infection through the eye as on the cerebellum or the sciatic nerve. The animals thus treated had only a slight rise of temperature, a transitory weakness and rigidity of the hind legs, while the control animals died of the infection. When the injection is made an hour after the infection, it has a curative action. After 24 hours it has no effect.—*La Riforma Medica,* May 6, 1905.

Acidification of the Liver and Spleen a Certain Sign of Death.—Brissemoret and Ambard call attention to the alkaline reaction of the liver and spleen in the living. This can be seen by experimenting with litmus paper of medium thickness. On the contrary, some time after death the reaction of these organs is acid, a reaction that increases progressively and rapidly. These investigators have studied this condition in nine cases—cancer of the stomach, cerebral hemorrhage, pulmonary tuberculosis, uremia, and puerperal septicemia. The reaction can be seen a half-hour after death if the experiments are carefully performed. The reaction is very persistent, for in one case of poisoning by strychnine, a state of considerable acidity was determined six months after death. The acidity of the liver after death is not due to microorganisms, but to autolysis, as has been demonstrated by Magnus Lévy. The acidity does not develop until about fifteen minutes after the cessation of respiration. At this time life is considered to be absolutely extinct. If uncertainty exists as to the presence of death in any instance, the examination of the hepatic or splenic pulp will satisfy all doubts.—*Revue Française de Médecine et de Chirurgie,* May 8, 1905.

Observations on the Local Treatment of Rabies.—Konradi, as the result of laboratory experiments with the disease, draws the following conclusions. It is possible to prevent the development of rabies by local antiseptic treatment (bichloride solution, 1-1,000) to the site of inoculation. In injuries to the limbs the treatment must take place within twelve minutes, and in wounds of the face within three minutes, but may be of value even after the expiration of thirty minutes. Relapses are possible with rabies, as with other infectious diseases. The virulence of rabic virus is reduced by active antagonism on the part of the animal organism. Individual susceptibility must be reckoned with in laboratory experiments, as in practice.—*Zentralblatt für Bakteriologie.*

Book Reviews.

Food Preservatives, Their Advantages and Proper Use; The Practical *versus* the Theoretical Side of the Pure Food Problem. By R. G. Eccles, M.D., Phar. D., Fellow of the American Association for the Advancement of Sciences, etc. With an Introduction by E. W. Duckwall, M.S., etc. New York: D. Van Nostrand Company. 1905.

The object of this little monograph is to show that food preservatives, such as salicylic or benzoic acids, are not injurious to health or digestion if employed properly, and that the opposition to their use comes from the ultra-conservative minds among the people and from politicians who are interested in the food problem without being acquainted with the scientific facts connected therewith. Dr. Eccles is not in sympathy with the majority of the leaders of the pure food and drug movement, for the opponents of modern preservatives appear to him to be in favor of impure food and food dangerous to public health. The essay is written, therefore, in the hope of convincing the profession and the public "that the evils that come from not using preservatives may be greater than those which can possibly result from their use."

The pamphlet makes interesting reading, and the author's reputation as a food expert entitles him to a careful and impartial hearing.

Poisonous Plants of All Countries. With the Active Chemical Principles Which They Contain and the Toxic Symptoms Produced by Each Group. By A. Bernhard Smith, late Acting House Surgeon to Lord Lister, King's College Hospital, London, etc. Bristol: John Wright and Company, 1905.

This is a syllabus of the poisonous plants commonly met with, and of the symptoms and treatment of the intoxications produced by them. Guy and Ferrier's classification of toxic plants has been followed, and under each group are given the names, botanical characters, and toxic principles of each plant and the symptoms and treatment of poisoning by any member of the group considered. A table of mushrooms, together with two rather primitive colored plates of fungi, are given, while a list of the active principles, a glossary of botanical terms, and a full index make the book useful for reference.

An Introduction to Chemical Analysis, for Students of Medicine, Pharmacy, and Dentistry. By Elbert W. Rockwood, M.D., Ph.D., Professor of Chemistry and Toxicology, University of Iowa, etc. Second Revised Edition. Illustrated. Philadelphia: P. Blakiston's Son and Company, 1904.

Dr. Rockwood's book is a practical manual of chemical analysis, intended primarily for medical students, as a guide in their laboratory course. It is probably too elementary for pharmaceutical students, except perhaps in the beginning of their course. The book includes an introductory chapter on general technics, and a series of lessons covering qualitative analysis of inorganic and of the commoner organic compounds, with special reference to the substances of interest to the physician. Volumetric analysis is next taken up, and its principles are thoroughly elucidated, so that a student can apply them later in his clinical work. Finally, a brief outline of the analysis of drinking water, of the methods of detecting poisons, and of blowpipe analysis is given. A series of tables useful to the beginner in chemistry completes the book.

The author correctly aims to teach principles rather than to fill the student's overtaxed cerebrum with a mass of details which he is not likely to retain. Special attention is given to incompatibilities of chemicals, and a series of suggestive questions has been inserted. The book is very practical, and evidently written to suit the peculiar needs of medical students. This second edition contains few changes, but has been carefully revised.

Infantile Mortality and Infant's Milk Depots. By G. F. McCleary, M.D., D.P.H., Medical Officer of Health in the Metropolitan Borough of Battersea. Illustrated. London: P. S. King & Son, 1905.

Dr. McCleary's book contains a very interesting and complete technical, statistical, and medico-humanitarian study of the movement known in France under the name of "Goutte de Lait," in England as "Infant's Milk Depots," and in this country typified by the philanthropy of Nathan Strauss and the work of various Health Boards in establishing "Milk Stations" for the infants of the tenements. The author studies the question of the milk supply to the infants of the poor from every viewpoint, collects a series of valuable statistics, and describes in detail the milk depots of France, England, Spain, and the United States. In England there is a tendency to follow American methods of modifying infant's milk, "without the American refinements, which are probably unnecessary on this side of the Atlantic," while in France the tendency is to give infants unmodified milk much earlier. A full account of the various phases of the pure milk movement in New York will be found in this book, including the "Certified Milk" system.

The book is especially to be commended to health officers and to physicians who are in charge of hospitals or other institutions for infants, but it is also of interest to philanthropists and students of preventive medicine in general.

Chirurgie du Système Nerveux (Crâne et Encéphale, Rachis et Moelle, Nerfs). Par Georges Marion, Professeur Agrégé à la Faculté de Médecine de Paris; Chirurgien des Hôpitaux. Paris: G. Steinheil, 1905.

This is the sixth volume of the system of surgery edited by Professors Berger and Hartmann of Paris, and contains the operative surgery of the cranium, the brain, the spinal cord, and the nerves. The work is based upon Professor Marion's personal experience, as well as upon the entire literature of the subject. The author assumes that the reader has little or no experience in this field of surgery, and leads him, step by step, through the operations, describing technical manipulations and instruments, landmarks, precautions, dangers, etc., with a minuteness of detail and a clearness of diction which makes the work especially valuable to the surgeon who only occasionally is called upon to perform operations on the brain and the spinal cord. The book is, however, also well adapted for the use of surgeons who make a specialty of brain surgery, as it presents all the methods known, with their bibliography, giving the preference in each instance to one or two selected methods which the author has found to give the best results in his own work.

The ground has been thoroughly covered, though naturally some subjects have not been treated completely, for the simple reason that they are still in a comparatively undeveloped state. The surgical treatment of epilepsy and other neuroses, and the newest methods of dealing with the cerebrospinal fluid, etc., are fully discussed. Americans have been given very full credit where it belongs, and one meets such names as McBurney, Nancrede, Hartley, Deaver, Keen, Dawbarn, etc. In discussing the resection of the Gasserian ganglion, the author gives due credit to both Hartley and Krause, but does not use either method personally, giving the preference to a procedure described in 1904 by Prat, which involves the resection of the zygomatic process.

The 320 illustrations are excellent, and add a great deal to the value of the book.

The Detection of Poisons and Strong Drugs, Including the Quantitative Estimation of Medicinal Principles in Certain Crude Materials. By Dr. Wilhelm Autenrieth, Professor in the University of Freiburg. Authorizes translation from the Third Enlarged German Edition, by William H. Warren, Ph.D., Professor of Chemistry, Medical Department of Washington University, St. Louis, Mo. Seventeen illustrations. Philadelphia: P. Blakiston's Son & Co., 1905.

In this volume, within the brief compass of a couple of hundred pages, the student will find a concise and valuable guide to toxicological analysis. The book is written by a well-known authority on the subject, and is here presented in English for the first time. In addition to the usual laboratory directions, the author gives information on the fate distribution, and elimination of the various poisons that may have gained access to the animal body. There is a sufficient indication of the literature of the subject, and constant reference is made to original articles dealing with special topics. The volume is well got up, the printing is clear, the arrangement excellent, and the book easily stays open at any given page—a necessary adjunct to a laboratory guide, but one not always found.

A Text-Book of Medical Chemistry and Toxicology. By James W. Holland, A.M., M.D., Professor of Medical Chemistry and Toxicology, and Dean, Jefferson Medical College, Philadelphia. Fully illustrated. Philadelphia and London: W. B. Saunders & Company, 1905.

This new book on chemistry has some features which differentiate it from most other books of its class. It is eminently readable; the various theories discussed are made clear and intelligible; there is not too much chemistry, and what is given has been selected with reference to the needs of the general practitioner; there are several sections of great practical interest, such as those on water supply, urine, milk, and the various paragraphs on toxicology, all of which are treated from the standpoint of the physician and not of the expert. Among the newer topics are included ionization, dissociation, cryoscopy, radium and radioactivity. A few flaws have been detected which could be corrected in the next edition, *e. g.* on page 60 the valence of boron is given as four; four pounds of sulphur will disinfect a space of 1,000 cubic feet, not 10 cubic feet, as on page 149; on page 131, hydrochloric acid should not be given as an example of the *-ic* acids with salts terminating in *-ate*.

Society Reports.

NATIONAL ASSOCIATION FOR THE STUDY AND PREVENTION OF TUBERCULOSIS.

First Annual Meeting Held in Washington, D. C., May 18 and 19, 1905.

(Special Report to the MEDICAL RECORD.)

(*Continued from page* 835.)

GENERAL MEETING.

THURSDAY EVENING, MAY 18.

Address.—Mr. TALCOTT WILLIAMS of Philadelphia said that the rise in the standard of life was chiefly due to the lessening of transmissible disease. He believed that in the future it would be as hard to find a case of tuberculosis for clinical study and the teaching of students as it is today to find a case of smallpox or typhoid fever in some European cities. He believed it would be the duty of the State in a short time to take care of all transmissible diseases, and the physician would confine himself to the treatment of the regular diseases of childhood, middle life, and old age. One of the most important factors in the removal of tuberculosis, in his opinion, was the elimination of dust, and he considered that greater care of our servants was most important. He urged the more thorough and careful investigations by hospitals and private subscribers of each individual case, and stated that the child is already born who will see tuberculosis disappear as a menace to society.

PATHOLOGICAL AND BACTERIOLOGICAL SECTION.

MORNING SESSION, FRIDAY, MAY 19.

Channels of Infection in Tuberculosis.— Dr. WM. H. WELCH of Baltimore reviewed in detail the various channels of infection, and the many and varied opinions of observers, both here and abroad, as to the relative frequency of each.

Dr. LEONARD PEARSON of Philadelphia called attention to the fact that an English Commission had recently stated that one-third of the cases studied by it were apparently due to the bovine tubercle bacillus.

The Clinical Value of Marmorek's Antituberculous Serum.—Dr. ARTHUR J. RICHER of Montreal gave statistics showing the results of the use of this serum, and explained in detail the method of its employment.

The Serum Diagnosis of Tuberculosis.—Dr. HUGH M. KINGHORN of Saranac Lake gave the details of the use of this serum, and stated that he did not rely upon it as being of much value.

The Diagnostic and Prognostic Value of Agglutination in Tuberculosis.—Drs. M. P. RAVENEL and H. R. M. LANDIS of Philadelphia did not consider that agglutination was of any value for diagnostic purposes, nor did it have any prognostic value.

Studies in Immunity in Tuberculosis.—Drs. E. R. BALDWIN, H. M. KINGHORN, A. H. ALLEN, and J. L. NICHOLS of Saranac Lake read these papers, in which they detailed a number of experiments, but drew no conclusions.

The Blood in Tuberculosis, with Special Reference to Prognosis.—Drs. JOSEPHUS ULLOM and F. A. CRAIG of Philadelphia read a paper in which they said there were many differences in the results obtained by examinations of the blood according to the stage of the disease.

The Thyroid Glands in Tuberculosis.—Dr. M. B. STANTON of Philadelphia reported having studied cases in the living and on the cadaver, and called attention to the frequency of the coexistence of disease of the thyroid and tuberculosis.

Dr. EDWARD L. TRUDEAU of Saranac Lake reported having observed the coexistence of tuberculous symptoms and exophthalmic goitre.

AFTERNOON SESSION, FRIDAY, MAY 19.

The Natural and Artificial Protection of Man Against Tuberculosis.—Dr. G. FIGARI of Genoa presented this paper by invitation; it was read by Dr. James J. Walsh of New York. It dealt with experiments made upon animals, and he hoped to produce a protective immunity against the disease by using certain fluids by the mouth, as blood serum, or milk. In other words, animals were to be immunized and the blood serum or milk of these animals was to be used to immunize a large number of people. Nothing positive in the way of conclusions was drawn.

Tuberculosis of the Thoracic Duct and Acute Miliary Tuberculosis.—Dr. WARFIELD T. LONGCOPE of Philadelphia read this paper, and said that many observations had been made of tuberculosis of the thoracic duct in cases of acute miliary tuberculosis. In 12 out of 13 cases of acute miliary tuberculosis large cheesy nodules were found in the duct. They had studied 25 cases of tuberculosis in which the process was generalized and where the thoracic duct seemed to be the origin of the process. Of these 25 cases, 17 were typical instances of acute general miliary tuberculosis. The course of the disease was usually from two to twelve weeks. In 20 out of 23 cases of generalized tuberculosis showed tuberculosis of the thoracic duct; in two instances of chronic type the peritoneum and thoracic duct were normal. The type of lesion in the duct varied greatly. He believed the thoracic duct was of great importance in spreading tuberculosis throughout the body. Two specimens of tuberculosis of the thoracic duct from the Johns Hopkins Laboratory were shown.

The Vitality of the Tubercle Bacillus in Sputum.—Dr. DAVID C. TWICHELL of Saranac Lake reviewed the literature on this subject, and told of experiments made with the tubercle bacilli in sputum to determine their vitality under various conditions of dampness or sunlight, in certain media, etc.

Vicarious Action of the Bowel for the Kidney in Tuberculosis.—Drs. LAWRENCE F. FLICK and JOSEPH WALSH of Philadelphia presented this paper, which was read by Dr. Walsh. They said they had made a careful study of a number of cases, which had been under observation for a long time, and had seen many cases come to autopsy, and they were satisfied that there existed this vicarious action of the bowel for the kidney in tuberculosis which seemed to be an effort on the part of Nature to eliminate by the bowel what could not be eliminated by the kidneys. A detailed report of one out of fourteen cases was presented.

Dr. OLIVER A. BLUMENTHAL of Syracuse reported a case of vicarious action of the bowel occurring in a patient of 28, who was suffering from tuberculosis of the left apex. About 7 o'clock in the evening the temperature would begin to rise, and by 8 o'clock it would be 102° or higher; this would immediately be followed by colic and rumbling in the bowel, and then by loose stools and the reduction of the fever. This reduction of temperature to normal would occur within a few minutes. Vicarious sweating was also noticed at times in this patient.

Landry's Paralysis Complicating Tuberculosis.—Dr. D. J. MCCARTHY of Philadelphia contributed the history of mixed infection occurring in a case of advanced tuberculosis. Landry's paralysis was an ascending paralysis, without sensory disturbances, with the toxic condition suddenly coming on and with the cerebrospinal fluid containing different microorganisms. In the case reported, the Klebs-Loeffler bacilli were found in pure culture. Landry's paralysis complicating tuberculosis was an exceedingly rare affair.

SOCIOLOGICAL SECTION.

SECOND DAY, FRIDAY, MAY 19.

Progress of the Sanatorium Movement in America.—Mr. WM. H. BALDWIN of Washington gave statistics of the number of sanatoria in existence at the present time throughout the United States, together with their location, accommodation, and results. He reviewed the growth of the movement from the time it was started twenty years

ago by Dr. Trudeau, and showed not only what had been accomplished up to the present time, but what the prospects were for the future.

Dr. W. J. Marcley of Rutland, Mass., took up the question of the employment of the improved cases and discussed it at great length. He also urged the improvement in the methods of living on the part of consumptives, and advised that physicians, Boards of Health, employers of labor, owners of buildings, and proprietors of sanatoria should be urged to cooperate in accomplishing this object.

Dr. J. N. Hurty of Indianapolis showed how Indiana was endeavoring to improve the condition of its consumptives, largely by educational means, and he advised the taxation of the owners of all unsanitary places as a means of increasing the healthful surroundings for consumptives to live and work in.

Dr. Kennedy of New York described a method now in vogue of finding employment for improved consumptives.

Dr. W. H. Allen of New York detailed the work of the seaside camp now in operation, and dwelt with great force and at considerable length on the importance of making the fact public that many of the deformities of childhood were due to tuberculosis in the parents.

Dr. Wallace of New York explained the objects of the seashore home at Coney Island for the treatment of crippled children, and detailed some of the results obtained to date.

Dr. T. E. Oertel of Augusta, Ga., stated that nothing of any importance in this matter had been done in the South, but that the profession was about to be organized throughout Georgia with a view of securing State aid and making a determined fight for the improved condition of the consumptive.

Dr. Wainwright of Scranton referred briefly to the philanthropy of a gentleman in Oil City, Pa., who was supporting several consumptive patients at his own expense in tents in the country, and feeding them at his own farm house.

Mrs. James E. Newcomb of New York made a few remarks as to what she and her associates were endeavoring to accomplish in New York City.

Dr. S. A. Knopf of New York gave more details of Mrs. Newcomb's work, which he said consisted principally of caring for poor consumptive working girls and women.

Dr. Geo. M. Sternberg of Washington, D. C., called attention to his establishment of a hospital for consumptive soldiers, instead of their having to be treated along with soldiers sick of other diseases. He also laid great stress upon the fact that to date it had been impossible to get any help from the Government for the establishment of a tuberculosis hospital in Washington.

Mr. Edward T. Devine of New York said the citizens of Washington would be able to accomplish more if they were to band themselves together, and not, as seemed to be the case, be at variance with the local Health Officer.

Dr. Kober of Washington agreed with Mr. Devine, and showed how impossible it had been to secure the condemnation of houses in Washington that were unfit for habitation, simply because one Senator objected.

Infection in Transportation.—Dr. H. M. Bracken of St. Paul went into this matter in great detail, especially concerning the condition of Pullman cars, and read extracts from letters from railroad surgeons all over the country, showing how little care in most cases is taken to keep the cars clean. He considered that sleeping cars were especially dangerous, and he believed the question of car sanitation and car ventilation was one of vital importance.

Dr. T. R. Crowder, a representative of the Pullman Company, objected to a great deal of what had been said in reference to the uncleanly condition of Pullman cars and the many criticisms of the Pullman car as now constructed. He called attention to the number of improvements that had been instituted within the last five years, of which he considered the most important was that of using a third sheet for covering over the top of the blankets, thus protecting the berth material entirely from the occupant and preventing the materials themselves from coming in contact with any future occupant. He explained the methods at present in use for the cleansing and fumigation of the cars, and admitted that an ideal method had not yet been found.

Dr. Bracken called attention to the fact that the car cleaning was not always done according to the rules regulating this work.

Dr. Crowder stated that the rule of the company that no infectious disease should be carried could not always be enforced.

Mr. Kennedy felt that perhaps the public's taste for ornamentation had something to do with the present make-up of the cars.

Dr. J. N. Hurty of Indianapolis commented on the fact that many people who traveled in Pullman cars were not cleanly themselves. He said he felt that the company was bringing about improvements as fast as possible, and that the condition of the company's blankets was sometimes better than the garments of the people who used them.

Mr. McDonnell, a representative of the Pennsylvania Railroad, assured those present that his company was anxious and willing to carry out any suggestions for the improvement and comfort of the traveling public that the association or any one else might suggest, provided it could be convinced of the necessity and practicability of adopting the suggestions offered. He showed that the company had gone to great trouble and expense in introducing the most up-to-date ventilator device; had made hundreds of tests in order to discover the best disinfectant, and was now about to devise a method of giving the traveling public a good reliable water supply in places where it was known that the drinking water was not good.

Dr. J. B. Castor of the Santa Fé Road stated that his company would gladly adopt any practical suggestions that might be offered for the disinfection, fumigation and cleansing of the cars and for the protection of the health of the traveling public. He called attention to the fact that the employees of the company were very rarely affected with tuberculosis, which was also true of the Pullman car employees, which he felt showed that the railroad cars could not be the menace to public health that it was claimed they were. He ridiculed the suggestion of having a hospital car for tuberculous patients, which, he said, would be useless in the absence of the law compelling such patients to ride in such cars.

Dr. R. L. Graham of New York spoke at some length on the methods employed by the Metropolitan Street Railway Company of that city to insure the health and comfort of the traveling public, and also called attention to some of the difficulties that had to be contended with in accomplishing the object sought.

Dr. Victor C. Vaughan of Ann Arbor said that the railroad companies, and especially the Pullman Car Company, were not doing by any means all that could be done to preserve the health of their passengers, and made several suggestions as to what might be done to improve the comfort and convenience, as well as lessen the dangers to the traveling public.

Mr. Edward T. Devine of New York suggested that this association should have a Standing Committee on Sanitation and Transportation, with Dr. Vaughan as chairman, and that the public should be educated up to the point of creating a demand for the improvement suggested.

Dr. Charles L. Minor of Asheville heartily endorsed the suggestions of Mr. Devine, and called attention to the fact that the railway surgeons were absolutely helpless in these matters, as their suggestions were always swept aside in order to place a few more dollars in the pockets of the stockholders.

Dr. Pottinger of Los Angeles commended the excellent sanitary laws and regulations of the Northern Pacific Railroad, and also the recent employment of the third sheet by the Pullman Company.

Dr. S. A. Knopf of New York called particular attention to the cuspidors in railroad cars, which he said were not deep enough, nor did they have large enough openings. In addition to these improvements, he recommended that something more than water should be placed in each cuspidor. He also objected to the habit of the Pullman porters in brushing off the passengers, which he considered a very dangerous procedure.

Dr. Bracken heartily endorsed what Dr. Knopf had said in reference to the cuspidors, which he said a person could not hit if he tried. He realized the difficulties of keeping the cars clean, but stated that this was accomplished in Texas because it was made compulsory.

Dr. Keim of Iowa moved that the thanks of the assembly be extended to the various transportation companies that had sent representatives to this meeting to take part in the discussion. This motion was carried.

Clinical and Climatological Section.

first day, thursday, may 18

The Secretary, Dr. S. G. Bonney took the Chair in the absence of Dr. Bridge, whose address "On Some Usually Neglected Dangers from Sputum," was read by title.

The Committee on Clinical Nomenclature made a report through its Chairman, Dr. Vincent Y. Bowditch of Boston, Mass.

Dr. Charles L. Minor of Asheville moved that the Executive Committee be requested to send copies of the report of the Committee on Clinical Nomenclature to the medical members of the Association and to the leading medical journals of the country; that they urge its general use during the coming year and that any resultant statistics be sent to the Committee on Nomenclature, which is hereby continued with orders to report next year. This resolution was carried.

The Committee on Early Diagnosis made a report, through its Chairman, Dr. Arnold C. Klebs of Chicago, Ill. The report called attention to the importance of family history, temperature, and careful physical examination. The Committee did not feel that the *x*-ray was of any particular value as an aid to diagnosis. Reference was made to the fact that the pleuritic friction sound was often heard early in the disease and also that râles were frequently heard only after the patient coughed. Some comment was made on the use of tuberculin which was considered quite important but necessitated great care and a complicated apparatus.

Dr. Edward G. Janeway of New York believed that the failure to recognize the disease in its early stages was partly due to lack of care and reexamination. He called attention to the fact that in the absence of physical signs a physician will often tell a patient he has no consumption, apparently forgetting that the disease might be present although physical signs were absent. He advised at least four or five examinations before a person should be pronounced free from consumption.

Dr. F. I. Knight of Boston believed that diagnosis had been attempted much earlier since the possible curability of the disease had been proved, and usually with beneficent results to the patient although occasionally otherwise.

Dr. DeLancey Rochester of Buffalo said the profession neglected the pulse entirely too much, and he believed a perceptibly increased pulse of low tension was an important sign. He reported in detail the case of a man in whose expectoration tubercle bacilli were present although a deformity of the nose and the condition of the pharynx would easily have accounted for the sputum he was raising and the symptoms of which he complained. Later examination of this patient elicited signs of early tuberculosis. He believed that all cases with a rising temperature should be examined repeatedly, as he considered this a most suspicious sign.

Dr. Potter of Indianapolis had asked the members of the junior class in a medical school to state the symptoms and physical signs of early tuberculosis, and although he had received very fair answers to the first part of the question he was appalled to observe the lack of knowledge concerning the early physical signs. Taking up the question of the use of tuberculin as a diagnostic agent he admitted that he had been led to use it more and more, especially in cases requiring a positive diagnosis at once.

Dr. Howard S. Anders of Philadelphia referred to the association of mitral stenosis with tuberculosis and mentioned two cases in which the patients, both semiemaciated, anemic women, with streaks of blood in the sputum, appeared to be tuberculous, but who really had mitral stenosis. The mitral stenosis was followed by apical tuberculosis six months later. While he did not know whether or not people suffering with mitral stenosis were any more susceptible to tuberculosis, yet he did feel that the type of physique rather indicated this. He then called attention to some of the mistakes made in physical examination, such as auscultation after the patient had taken two or three deep breaths, when one might miss things that had been present before.

Dr. Alfred Meyer of New York said that he avoided the auscultatory mistakes mentioned by Dr. Anders by making a second examination of suspected points after he had made a cardiac examination. Referring to the occurrence of hemoptysis in mitral stenosis he said he knew that in cases in which mitral stenosis and areas of dullness coexisted hemoptysis had often been present.

Dr. S. E. Solly of Colorado Springs regretted very much the slighting way in which the *x*-ray had been treated in the report as he regarded it as extremely valuable and often of great service.

Dr. Charles L. Minor of Asheville called attention to the use of the thermometer. He advised that physicians should make sure their thermometers were accurate on some other authority than that of the maker. He commended the Committee for dwelling in their report upon the importance of the use of the blue pencil, as in his opinion it was only by its aid that one could satisfactorily determine these cases.

Dr. S. L. Pottinger of Los Angeles thought that with the physical examination, personal history, and tuberculin test the diagnosis could be made with a practical certainty, although it required considerable time.

Dr. John H. Pryor of Ray Brook, N. Y., regarded the Committee's report as one of the safest and most judicious he had ever read, and in view of the fact that it would probably be published he suggested that it be so changed as to include a reference to the change in the pitch of the voice or whisper as a diagnostic point.

Dr. Mannheim of New York emphasized the point that rough breathing was the very earliest sign of tuberculosis, but called attention to the fact that it must not be confounded with increased vesicular breathing, interrupted breathing, or adventitious sounds. While this sign was not absolutely characteristic of tuberculosis yet in his experience it was often found after repeated examination.

Dr. Dunn expressed the fear that physicians might go a little too far into the refinement of diagnosis, and misinterpret the slight signs, calling them indications of tuberculosis, although he did not mean to decry the most careful work in this line.

Dr. Arnold C. Klebs of Chicago, in behalf of the Committee, thanked all those who had taken part in the discussion and said the Committee simply wanted to bring out in its report the most important points.

Dr. DeLancey Rochester of Buffalo moved that the relation of tuberculosis to insurance companies and the importance of the cooperation of these companies be brought to the attention of the officers of this Association; that they be requested to interest the directors and officers of the insurance companies in the matter of the prevention of tuberculosis, and that an invitation be extended to the officers to attend the next annual meeting of this Association. This was carried.

On motion of Dr. Victor C. Vaughan of Ann Arbor the report was adopted as read.

The Open Air Treatment of Surgical Tuberculosis.—Dr. W. S. Halstead of Baltimore in this paper referred to the early treatment of tuberculosis, especially surgical cases, by means of open-air life, and quoted at length a large number of illustrative cases.

Dr. John W. Brannan of New York detailed the results of the work done along this line at Coney Island where an institution had been established for open-air treatment, which showed it to be a great success. He stated that the children were kept out of doors every day in the year and slept every night with the windows down, the temperature in their rooms at times being as low as 28°. He showed some photographs of some of the children illustrating marked improvement and gave some statistics of the results accomplished to date.

Dr. Alfred Meyer of New York asked if the use of tuberculin was as beneficial in tuberculosis of the bones as in tuberculosis of the soft parts and requested an explanation of the method of its administration.

Dr. Halsted said that Dr. Trudeau's preparation and method were employed, two milligrammes being given to an adult and one to a child to begin with, the second dose being increased to four and two milligrammes respectively, a third dose being very rarely needed.

Influence of the Advent of the Tuberculous Upon Native Populations.—Dr. C. F. Gardner of Colorado Springs referred in this paper to the great difference in different countries and cities in the effect on the native population of an influx of consumptive cases.

Dr. Lawrence F. Flick of Philadelphia believed that the reason why the native population in many places was not affected by the invasion of tuberculous people was because of the immunity enjoyed by the descendants of consumptives. He stated that children were more immune than parents and that therefore the children of consumptives were less susceptible to the disease than the parents were, which he thought perhaps explained why, in a thickly populated city like Denver, there were not more cases of tuberculosis among the natives.

Dr. S. L. Pottinger of Los Angeles said that only two cases of tuberculosis, so far as could be learned, had occurred in the native population of his city in the last ten years, although attention had frequently been called to what might happen if tuberculous cases were herded together in cheap lodging houses.

The Committee on the Role of Climate in the Management of Tuberculosis made a report through its Chairman, Dr. Charles L. Minor of Asheville.

Dr. Lawrence F. Flick of Philadelphia objected very much to the adoption of the report on the ground that the Committee had considered climate an important factor in the treatment of tuberculosis whereas the speaker did not consider there was anything in climate in the treatment of this disease. He believed that common sense ways of living with open air, proper diet, and proper discipline, in any kind of climate, would effect a cure, and made the statement that he had sucessfully treated in Pennsylvania patients who had been unsuccessfully treated in the West and the South.

Dr. F. I. Knight of Boston thought that climate did have some effect in the treatment of the disease.

Dr. Stevens of Iowa urged that the report should be so modified as to lay less emphasis on the value of climate as he feared otherwise the publication of the report would have a bad effect on legislators when they were approached on the question of establishing sanatoria in their own States.

Dr. Carrington of Fort Stanton spoke strongly in favor of climate in the treatment of tuberculosis largely because in certain places one could live out doors so many more days in the year than was true of certain other places.

Dr. Vincent Y. Bowditch of Boston spoke in favor of adopting the Committee's report.

Dr. DeLancey Rochester of Buffalo, while claiming that he had had some patients recover from tuberculosis while living in the damp and dark city of Buffalo, admitted that it was not the place where he would elect to treat a patient if he could be sent elsewhere, and he was therefore in favor of adopting the Committee's report.

Dr. Guy Hinsdale of Hot Springs, Va., asked what the members of the Association would do if they had consumption and, replying to his own question, stated that they would doubtless seek the best climate they could get.

Dr. Alfred Meyer of New York thought it was a good thing that objection had been taken to the report of the Committee as it had accentuated in the minds of those present the value of pure air.

Dr. Lawrence F. Flick of Philadelphia believed that a patient could live out of doors 365 days a year in any climate, never mind how severe or damp the weather, as it stimulated the desire for the very kind of food that was necessary for the treatment of the disease.

Dr. W. F. R. Phillips of Washington was in favor of referring the report back to the Committee owing to the great difference of opinion as to the value of climate on which the Committee had laid considerable stress.

The report was finally adopted although with many dissenting votes.

SECOND DAY—FRIDAY, MAY 19.

The morning was devoted to a symposium on the sanatorium treatment of consumption.

Sanatorium Provision with Industrial Opportunities for Indigent Consumptives.—Dr. Herbert M. King and Dr. Henry B. Neagle of Liberty, N. Y., presented this paper which was read by Dr. King. All exertion, physical as well as mental, should always be under medical advice and a list of occupation more especially adopted for consumptives was given. In the institution at Liberty there were three departments, the infirmary, the pavilions, and the industrial. Patients were first sent to the infirmary under medical supervision. When the disease became quiescent the patient was transferred to the pavilion before it was determined the kind of work best adapted for him. As the disease abated he was transferred to one of the units of the industrial departments, and later he was sent back to the world a bread winner. At the Loomis Sanatorium the average duration of the disease was over three years, and during these years 70 per cent. of the fifty people chosen for observation were self-supporting. To determine the merits of complete rest and exercise some experiments were made in the Loomis Annex which seemed to favor the enforcement of rest. In only a few instances the patients felt better during the period of increased exercise. In 1902 an attempt was made to create a working corps among the quiescent cases, caring for the live stock, etc., each patient working four hours a day divided into two or four shifts, but the plan had to be abandoned because of disinclination on the part of the patients. Moderate exercise under careful supervision was most beneficial in certain cases.

Detention Institutions for Ignorant or Vicious Consumptives.—Dr. J. P. C. Foster of New Haven read this paper. He believed that it was not so very important to draw a sharp line of distinction between the ignorant and the vicious consumptives; they should be properly recorded and the unfortunate cases should be kept under supervision. Pauper cases passed into charitable institutions to remain there for life, and this became with a patient a matter of choice. For the safety of the public the right to detain such cases in hospitals should be given, and should be rigidly enforced. The detention of those willing to work was a different matter, although sometimes it must be necessary to detain patients who were able to work. These, he said, were the most dangerous that they had to deal with. With regard to the proper places for such detention, rationally the place was properly equipped wards in the poorhouses. Detention institutions could be had at very small expense and residence in such institutions should be demanded of such patients. The vicious consumptive could be held in the ordinary jails at slight expense and he should be made to do some work, as keeping the rooms clean, etc. Forcible

detention should be made for those who were endangering the community.

What Cases are Suitable for Admission to a State Sanatorium for Tuberculosis Especially in New England.—Dr. H. C. Clapp of Boston read this paper in which he related his experience of six and a half years at the State Sanatorium at Rutland, Mass. The cases that were entered early in the disease showed 75 per cent. cures; the far-advanced cases were never cured; moderately advanced cases could sometimes be cured but often not. The incipient case should be made the standard for admission but, of course, this standard was more or less flexible. These hospitals should not be turned into homes for incurables. The sanatorium at Rutland had been gradually increasing its accommodations, starting in 1898 with 175 beds and now having 325 beds and soon it would have 400; if there had been no enlargement of accommodations the sanatorium would now be filled with incipient cases. Certain cases were positively excluded, such as the bed ridden, those with high fever, with laryngeal complications unless very small, with complications of other organs as the kidneys, etc. The vital point was the nutrition; this was the sine qua non of treatment and, therefore, any case with marked digestive disturbances was refused admission. No children under 14 or adults over 50 were admitted. The apyretic were the most desirable cases.

Six Years' Experience at the State Sanatorium for Tuberculosis at Rutland, Mass.—Dr. V. Y. Bowditch of Boston and Dr. H. B. Dunham of Rutland presented this communication which was read by Dr. Bowditch. He said hopeless cases were not received in this institution but provisions were made for them elsewhere. The majority of the cases admitted were far away from the incipient stages of the disease. Since the institution had been opened in October, 1888, there were received 3,300 patients out of 7,000 applicants, and for the results of treatment he referred them to the Eighth Annual Report published in 1904. He presented the following table: The number of patients discharged with disease arrested, 539; in good health and most of them at work, 400; the number who had not replied to his letter if inquiry, 50; the number of patients who could not be traced, 9; the number in whom the symptoms had returned, 36; the number who died, 45; patients who left the sanatorium "improved" but who had now reached the condition of "arrested," 63; this made a total of 1,142. This table showed the subsequent history of the patients up to May, 1905.

Sanatorium Management in Appropriate Climates.—Major G. E. Bushnell of Fort Bayard, N. M., read this paper. The cases dealt with were from the army, navy, and marine-hospital service largely and one-third of the cases were able to care for themselves unwatched. Many of the cases admitted were almost moribund and the results in this sanatorium should, therefore, not be compared with other institutions. At Fort Bayard the altitude was 6,040; the air was dry and but a slight precipitation; the rainfall was 13.79 inches and occurred chiefly in the summer months. The climate here was very advantageous and there was less sunshine during the summer months. The chief contraindication to altitude was weakness of the heart; increased strain upon the heart caused many cases to die quicker than if they lived at lower elevations. All patients were required to rest for one month when admitted and the results justified this procedure. The results of treatment here were very good. Photographs were shown of hospital plans and arrangements. In 1904 there were 625 patients, 375 remaining under treatment at the close of the year. Among these 625 cases there were the following results: In 12 there was arrest; in 379 there was improvement; 173 were unimproved; 61 died; 61 were not under continuous treatment. The cases in the Philippines did not differ in prognosis from the cases met with in this country.

The Treatment and Care of Advanced Cases of Pulmonary Tuberculosis.—Dr. S. A. Knopf of New York read this paper (to be published later).

The Home Treatment of Tuberculosis in Either Favorable or Unfavorable Climates.—Dr. Edward O. Otis of Boston read this paper and said that no climate for the treatment of tuberculosis was a favorable one, and that we should speak of climate in this connection as being "more favorable" or "less favorable." It had been stated that only 2 per cent. of those afflicted with tuberculosis could take advantage of sanatorium treatment and therefore the home treatment became of the greatest importance. Dr. Otis considered the question under different headings or divisions; the desperately poor, those who were in most comfortable circumstances while engaged in work, but whose incomes ceased when out of work, those able to go away, but with strong disinclination to go away, and those able and willing to go and live elsewhere, but who preferred to be treated privately. Each of these classes he said must be treated differently, and the hygienic and dietetic treatment must be adopted according to the exigencies of the case. The importance of cultivating a merry heart to make a cheerful countenance was emphasized. Pulmonary gymnastics was found to do more harm than good by many and Dr. Otis was of the opinion that restriction of motion and not increased motion was better for patients suffering from pulmonary tuberculosis.

The After Treatment of Tuberculosis.—Dr. J. A. Wilder of Denver read this paper.

The History and Work of the Bedford Sanatorium of the Montefiore Home.—Dr. Alfred Meyer of New York read this paper (to be published later).

Clinical Suggestions from the Study of Five Hundred Cases of Pulmonary Tuberculosis.—Dr. H. P. Loomis of New York read this paper (to be published later).

The Educational Leaflet for Distributon Among the People.—Dr. H. B. Biggs of New York, Dr. William B. Stanton of Philadelphia, Dr. V. Y. Bowditch of Boston, and Dr. Joseph Walsh of Philadelphia, were the members of the committee, which made the introductory report on this leaflet. This report was followed by a lengthy discussion as to the needs which should be fulfilled by such an educational leaflet for the people.

TENNESSEE STATE MEDICAL ASSOCIATION.

Seventy-second Annual Session, Held at Nashville, April 11, 12, and 13, 1905.

The Association met at Watkins' Hall, under the Presidency of Dr. Paul F. Eve of Nashville.

Prayer was offered by Rev. W. M. Anderson. Addresses of welcome were delivered on behalf of the city by Mayor A. S. Williams, and on behalf of the medical profession of Nashville by Dr. Geo. H. Price, the response to which was made by Dr. H. Berlin of Chattanooga.

Melancholia.—Dr. S. T. Rucker of Memphis read a paper on this subject. He defined the disease, and then referred to the etiology, symptoms, varieties, pathology, diagnosis, prognosis, and treatment. The onset of melancholia was almost always gradual. At first, it might be only a feeling, which took no definite shape, and there might be no delusions. Every thought and everything in the environment had a sorrowful color. When questioned, the patient would simply say he felt depressed or he had the blues. The morbid feeling constituted the disorder. The symptoms varied from a simple state of dejection to a state of profound depression, in which the patient was either paralyzed by the dreadful nature of his concepts or was thrown into a state of agitated suffering, associated with marked precordial distress and peculiar pains in the back or top of the head. The prognosis in melancholia was very favorable. Fully 90 per cent. recovered. Thorough investigation, speedy separation from relatives and friends, and an early commitment to an institution for treatment should be the rule in this class of patients.

Dr. M. Campbell of Knoxville said that melancholia was not, strictly speaking, a mental disease, but a symptom of a pathological state that underlay the symptom of depression that was most prominent, whether it be an organic

or functional disease, but most generally it was functional. A large percentage of the subjects of melancholia who were sent to hospitals for the insane did not recover. He did not think half of them got well. As to the treatment, he suggested a change of scene, getting away from the conditions that produced the disease, building up the patient physically, giving hypnotics to produce sleep, warm baths, etc.

Dr. W. J. Breeding of Taylors related the history of a woman, 42 years of age, mother of eight children, whom he saw in the sixth week of pregnancy, when she was in a very depressed condition. He made a diagnosis of hysteria. There was no pathological condition, so far as could be determined. She had numerous delusions up to the seventh month of pregnancy, when a miscarriage occurred, the fetus being badly deformed. It was thought she would now get well, but in a couple of weeks she lapsed into a condition of melancholia, eked out a miserable existence for two or three months, and then committed suicide by hanging.

Dr. C. P. McNabb of Knoxville reported two cases, in neither of which would the family consent to sending the patient to a hospital. One patient had three attacks of melancholia, with three partial recoveries. The other was now in her third attack.

Dr. A. F. Paschall of Crossland thought that in the case of young men advertising literature played an important rôle in the causation of melancholia.

Dr. S. S. Crockett of Nashville said there was a popular impression that there was an insanity that developed in puerperal women that differed from other forms of the disease. There never was a greater mistake. Pregnancy and lactation should be regarded as one factor that might produce insanity in a woman who was otherwise predisposed to it.

Dr. Louis Le Roy of Nashville agreed with Dr. Crockett that there was no special type of insanity peculiar to the pregnant woman. The shock to the nervous system resulting from the profound changes occurring in pregnancy might bring on an attack which was impending or accentuate the nervous disturbance, otherwise held under control. On the other hand, many cases were the result of autointoxication.

Diagnosis of Kidney Diseases.—Dr. Louis Le Roy of Nashville read a paper with this title, and among other things, said that while malformations of the kidney were of great rarity, their importance in surgical cases should cause the possibility to be constantly borne in mind. The absence of one kidney or fusion of both into one mass should be considered, and the presence of an organ on both sides determined, if possible, while debating the admissibility of operative measures. It was not always possible, and frequently quite difficult, to determine the presence of the kidney when in normal position, and in such cases the presence of the organ might be determined by the *x*-rays, or both ureteral orifices might be determined by a cystoscopic examination, in which case the presence of two kidneys might be considered as assured. In case of movable kidney, however, it was usually possible to recognize the condition by palpation, sometimes assisted by percussion, and one might sometimes be surprised to find no clinical symptoms associated. In appendicitis the location of the point of tenderness, the usually higher temperature, absence of blood in the urine, tenseness of the muscles of the abdomen and flank, and the increase of polymorphonuclear leucocytes in the blood should direct attention from the kidney, especially if the mass could be palpated. Renal neuralgia was usually found in patients of a more or less neurotic temperament, and would not be found to be associated with hematuria. Ovarian inflammation might be puzzling, but one would usually be able to elicit some exciting cause, and local tenderness should be easily recognized by vaginal examination. Hematuria was absent and some endometritis was frequently associated. Diaphragmatic pleurisy would usually be influenced somewhat by respiration, even though the diaphragm were held rigid. There would be absence of abdominal breathing, and cough was usually present. The respirations were usually shallow and hurried, and early in the attack auscultation would frequently elicit the friction sounds. The essayist described the points of differentiation of kidney diseases from gastric ulcer, ataxia, chronic valvular diseases of the heart, and then referred at length to acute parenchymatous nephritis, and acute interstitial nephritis. Pyelonephritis was usually secondary to some other infection below, but especially in typhoid fever and tuberculosis might originate through the blood.

Perinephritic Abscess.—Dr. W. A. Bryan of Nashville discussed this subject, and the differentiation of this form of abscess from other abdominal conditions.

Treatment of Hypertrophied Tonsils.—Dr. J. P. [illegible] of Memphis entered his protest against the promiscuous and wholesale excision of children's tonsils. There were three kinds of diseased tonsils: (1) A tonsil which was constantly swollen, red, and easily irritated; this tonsil was of a specific scrofulous or tuberculous nature, and the only logical method of dealing with it was by excision. (2) A tonsil which was diseased in the interior, which formed occasionally into an acute abscess. (3) A tonsil with ulcers on the surface, which might be either indolent or active, was easily managed by a 2 per cent. solution of nitrate of silver. As to treatment, tonsil No. 1 was treated by complete excision; tonsil No. 3, which had ulcers on the surface, could be relieved with 2 per cent. solution of nitrate of silver, but tonsil No. 2 gave considerably more trouble. His method of treating tonsils of this character was to pass a small curette through these openings into the bottom of the tonsil and remove all the diseased or granular tissue, then carry a 10 per cent. solution of nitrate of silver into the tonsil. This should be repeated in from three to six days, and continued until the tonsils were cured, which usually required six treatments. By this method the tonsils were cured and left to perform their natural functions. He laid down two general rules: (1) Cure all tonsils which can be cured, and leave them intact. (2) Excise all tonsils which cannot be cured.

Dr. J. T. Herron of Jackson, in a paper on the same subject, quoted from some of the best authorities to show the importance of removing hypertrophied tonsils by some operation, and not allow them to remain, thus weakening the mental and physical strength of boys and girls. He detailed a number of cases upon which he had operated with gratifying results.

Dr. G. C. Savage of Nashville said it was a great mistake to allow children to go on from year to year with enlarged faucial tonsils., especially if they were subject to repeated attacks of inflammation.

Dr. T. J. Happel of Trenton preferred a tonsillotome for removing tonsils. He had tried scissors and other instruments, but said the practitioner should select that instrument which was best adapted to his use, then the work could be done more successfully.

Medical Ethics.—Dr. T. J. Happel of Trenton read a paper in which he said it was to be regretted that most graduates left medical colleges with a vague sort of idea that there used to be in the dim past a set of rules governing the relations of medical men to one another, to their patients, and to the public at large, but that since nothing had ever been said to them by their professors upon this subject, those rules had long since passed into innocuous desuetude.

Origin and Treatment of Malignant Growths.—This was the title of the President's Address, delivered by Dr. Paul F. Eve of Nashville. He mentioned two varieties, one of the epithelial type of cells known as carcinoma; the other of the endothelial variety, or connective tissue cells, known as sarcoma. Both of these in many respects presented clinical features very much alike. He referred to the theory that cancer was of parasitic origin, but said he was very much more favorably impressed by the other

theory which based the origin of cancers upon cell proliferation. Assuming that this disease was due to cell proliferation, if one could in any way check or change these cells, he had the promise of an ultimate success and recovery. About two years ago he operated upon a lady for scirrhous mamma, with involvement of the neighboring glands. A very complete operation was made, and every vestige of the disease was removed, so far as could be discovered. Her recovery seemed complete in every respect, and he flattered himself that there would be no recurrence. Four months after the operation she returned with a reappearance in the scar tissue. A second operation was performed, consisting of curetting the diseased structures. The patient was subjected to treatment with the *x*-ray for four weeks. At first improvement was noticed, but at the end of the third week the wound looked very unhealthy, and at the end of another week the patient returned to him, appealings, as all those unfortunate women do, for some means to save her life. The appearance of the ulceration was foul and fungous, and every indication pointed to general infection and a speedy death. He began to treat this wound with balsam of Peru, after first irrigating with bichloride of mercury, 1-3,000. After the first few days the unpleasant odor ceased and he was surprised to notice a decided change and granulations of a healthy nature springing up in the wound. This treatment continued for five weeks, with an occasional touching up of the granulations with the solid stick of nitrate of silver. At the end of this time the wound was entirely healed, and the patient looked the picture of health. He had the pleasure of seeing this patient a short time ago. There was not the slightest evidence of any recurrence, and the woman was in excellent health.

Since this case he had had quite a number of others which had been treated in a similar manner. Improvement had been marked in every instance, and the ulcerations from the foul and fungous condition had assumed healthy granulations, healing occurring slowly but effectually.

Gastric Dilatation Without Stenosis.—Dr. Fenton B. Turck of Chicago discussed the pathology of this subject.

Food Adulteration in Tennessee.—Mr. Lucius Brown of Nashville, in a paper on this subject, said that an examination of pure food legislation showed that 22 States had a regularly organized food inspection department. Kentucky had just increased its appropriation for this purpose from $7,500 to $10,500. For the proper enforcement of pure food laws a qualified analytical chemist was an absolute necessity. Not less necessary was a wise and active pure food commissioner.

Early Diagnosis and Early Treatment of Otitis Media.—Dr. N. C. Steele of Chattanooga said that there was a large number of adults who were permanently deaf in one or both ears. Of every one thousand seriously deaf ears, perhaps in 999 the disease was otitis media, and every aurist knew that chronic otitis media was generally incurable. He pointed out the general management and treatment of these cases, and closed by saying that the physician who looked carefully and intelligently after the patient's general health, as well as the local treatment, would have the greatest success in otitis media, just as he would in other local diseases.

Tuberculosis Cutis.—Dr. J. M. King of Nashville discussed this subject. He pointed out how the initial skin lesion was formed, and discussed the differentiation of lupus from rosacea, eczema, and blastomycosis, which he said was rarely necessary. Radiotherapy, Finsen light, and violet rays were at present considered the most acceptable method of treatment, and should always be used if possible.

Gastrointestinal Diseases of Children in Summer.—Dr. Zeb. L. Shipley of Cookeville divided the acute diarrheas of infancy on the basis of their etiology into two main classes, namely, those due to nervous origin and those due to infection. Simple diarrhea was of nervous origin, manifested by an increased peristalsis. This increased peristalsis might be caused by various conditions acting through the central nervous system or by the mechanical action of undigested food. Among the most important factors acting through the central nervous system were sudden changes in temperature, prolonged exposure to heat or cold, fright, and fatigue. Food might fail of digestion from being unsuitable, or from the digestive organs being functionally weak. In either case the food became a foreign body. In this form of diarrhea the intestinal mucous membrane showed no pathological lesion unless it be a slight hyperemia. The stools were increased in number and fluidity, and usually contained particles of undigested food. The chief factor in the treatment of this form of diarrhea was the removal of the cause. If the alimentary canal contained undigested food, this could best be eliminated by giving fractional doses of calomel and sodium bicarbonate, often repeated, until one or two grains had been given, or castor oil in teaspoonful doses acted admirably. The cause having been removed, the diarrhea usually ceased. But should it continue, the treatment should be directed to the control of the excessive peristalsis. The author next devoted considerable attention to infective diarrhea, and said in the prophylactic treatment of it the infant should have the best possible hygienic surroundings, be given plenty of fresh air and bathed frequently. Care should be taken not to overfeed the infant, as less food was needed in warm weather than in cool, and owing to the depression produced by the heat the child was less liable to digest its food. The infant should be kept as quiet as possible. It should be lightly clothed and frequently bathed.

How Shall We Feed and Treat the Baby?—Dr. Herman Hawkins of Jackson, in a paper with this title, laid down three cardinal rules: (1) A food should be given the baby which could be assimilated and given at regular intervals. (2) One should obtain the best possible hygiene of person and surroundings. (3) As little medicine as possible should be given. Each rule was discussed at considerable length, and several cases were reported.

Amyloid Degeneration.—Dr. C. P. McNabb of Knoxville defined this disease and then discussed its etiology, pathological anatomy, symptoms, diagnosis, differential diagnosis, and treatment.

The More Serious Complications of Influenza.—Dr. E. A. Cobleigh of Chattanooga said that one of the primal results of influenza which was impressed upon him early was not simply the usual debility which accompanied most of the cases and seemed out of all reasonable proportion to the appreciable conditions presented, but its indefinite persistence and extreme degree in quite a good many cases. The patients, wholly without regard to age or previous vigor, were too feeble for any movement or exercise beyond the minimum of vitality required to stay alive. This one element of debility was profound, and the sole cause for uneasiness. Instead of recovering within ten days or a fortnight, most of these sufferers lingered for weeks, sometimes even for months, and not a few dwindled on for a year or two, to die of sheer exhaustion at last. The next condition, often occurring by itself, was marked by extreme nervousness. A third condition, not very frequent, but seen often enough to impress the clinician, was marked by mental involvement, occasionally amounting to prolonged delirium, to stupor little short of coma, to hallucinations during or even after convalescence from the real attack; and rarely to mania or continuing insanity. One of the most impressive and rare complications which he recalled ever having seen consisted in extreme clonic spasmodic seizures, particularly involving the heart, the diaphragm, and the muscles of respiration, with no mental disturbance except the most pitiable fear of impending death.

The Clinical Significance of Ascites.—Dr. Raymond Wallace of Chattanooga discussed this subject and reported two instructive cases. One case illustrated unusual difficulty of making an accurate diagnosis. The unusually pronounced alcoholic history in this case with excessive peripheral arteriosclerosis, taken with the gastric symptoms and the presence of ascites, naturally led to a diagnosis of

atrophic cirrhosis; and the absolute absence of any cirrhotic changes in the liver was a point of interest. The disappearance of the miliary carcinosis of the peritoneum after scrubbing and exposure to the air presented a phase analogous to the operative cure of miliary tubercle of the peritoneum.

Acute Septic Osteitis.—Dr. Jere A. Crook of Jackson reported a severe case of chronic osteomyelitis of the femur in a twelve-year-old boy. The disease had existed for a year, and the necrosis had progressed so far that the shaft of the bone was entirely consumed for about two inches. The ends of the remaining bone were rounded with bone forceps, all loose pieces removed, the two freshened ends put in apposition, drainage inserted, and the limb encased in splints. The result was unusually good. The bone united, the wound healed entirely, and the patient had a useful leg with only about three inches of shortening. Here amputation seemed indicated, but conservative treatment saved the limb. He had amputated only twice for ostemyelitis, and then after making every effort to save the limb.

Prophylaxis of Tuberculosis.—At the evening session of the second day, this subject was discussed largely for the benefit of the laity, and speeches were made by Dr. John A. Witherspoon, Rev. Collins Denny, Captain A. J. Harris, and Mr. G. H. Baskette, representing the lay press.

Gallstones in the Common Duct.—Dr. W. D. Haggard of Nashville read a paper on this subject. He said that gallstones in the common duct had been found once in every five cases operated by Robson, and once in every seven cases of the Mayos. It was estimated that 67 per cent. occurred in the duodenal end, 15 per cent. in the hepatic end, and 18 per cent. in the middle of the choledochus. They varied in size usually from a split pea to a nutmeg, although exceptional instances of much larger stones had been recorded. They were usually solitary, although more than one was frequently found. Freeman of Denver removed 37. They usually caused death in from six to twelve months from cholemia, if the obstruction was complete and unrelieved. He had seen death ensue in six weeks from cholemia and infection. Operation was not urged in acute obstruction by stone, but recommended in all cases that had been in existence for several weeks or longer, unless there were ecchymotic spots from long-standing cholemia. A quiescent interval between ague-like attacks and in the absence of jaundice, was recommended for operation, if such an interval could be attained.

Circumcision.—Dr. E. A. Timmons of Columbia read a paper on this subject, in which he discussed its technique, method of anesthesia, and after-treatment, and reported several cases.

Appendicitis.—Dr. John A. Gaines of Nashville read a paper on this subject in which he cited several anomalous cases of this disease.

Etiology and Pathology of Appendicitis.—Dr. Walter Lenehan of Nashville contributed a paper with this title, which was based on the examinateion of 12 cases which were reported in detail, after which the author discussed the etiology, predisposing causes, and immediate causes. He had found the following organisms in his cases: Bacillus coli communis, Streptococcus pyogenes, aureus, Staphylococcus pyogenes aureus, Bacillus influenzæ, Bacillus typhosus, Klebs-Loeffler bacillus, Bacillus tuberculosis, and Diplococcus pneumoniæ. Some non-pathogenic organisms, notably the gas bacillus and a few yeast fungi, were also found, but were invariably associated with one or more of the pathogenic organisms. The organism most frequently found was the colon bacillus. The author drew the conclusion that any microorganisms capable of producing inflammatory changes in any other part of the body might also produce the same changes in the appendix.

Laryngeal Diphtheria.—Dr. C. H. Wilson of Nashville emphasized the importance of early mechanical relief when mechanical obstruction threatened life, and held that one should not delay until depression was marked. While in no other operation did skill show to better advantage, intubation was not a difficult procedure, but could be learned easily by practice. An early operation, though possibly awkward, was better than waiting to give a moribund case to an important consultant. Moral: Don't wait; intubate.

Tabes Dorsalis.—Dr. G. P. Edwards of Nashville said that the treatment of this disease should be directed to the removal of any syphilitic processes present or suspected; to the improvement of the general health, to stimulation of the function of the cells impaired but not lost, to restoration of coordination in the muscular system, and to correction of any incidental disorders which might retard or complicate the desired result. The author believed that any stage or condition of tabes might be improved or benefited by properly directed treatment. The development of the degenerative changes could be arrested completely in nearly every preataxic case, and much of the lost function could be restored. He believed that these results might also be obtained in a large majority of the ataxic cases, and that this majority was reduced somewhat in proportion to the duration and intensity of the ataxia and the abuse of the specific remedies employed. The author's clinical observation, aggregating 14 cases in his private work, had been uniformly satisfactory. In these fourteen cases, embracing a variety of conditions and degrees of advancement, all had responded to treatment in a most satisfactory manner. In every case the disease had been arrested and continued so to the present time. The author had demonstrated that the *x*-ray, when of sufficient penetration to obliterate the shadow of bony structures, would stimulate cell activity in the diseased cord, facilitate the restoration of the lost function in cells not completely destroyed, and relieve the crises and other lightning pains.

Alcoholic Insanity.—Dr. I. A. McSwain of Paris offered the following suggestions on this subject: (1) The children of drunken and debauched parents ought for obvious reasons to be taken away from them and placed in decent homes, or removed to industrial institutions provided by the State. This would check their hereditary tendencies to drunkenness, and therefore reduce the number being raised up to become a burden to the State in the way of paupers, criminals, and lunatics. (2) Young people, who in early life contract the pernicious habit of drinking, should also be removed from the temptation of their environments, and placed in institutions in which they should be taught some useful employment and restrained from vicious habits. (3) The drinking man, as soon as he began his spree, before he was crazed by it, should be taken into custody, not as a mere nuisance, but as a dangerous man or one likely to become so, because of insanity in the incipient stage. (4) The confirmed drunkard, the chronic alcoholic subject, should on no account be allowed to exercise his personal liberty in the pursuit of delusions which result from prolonged excesses.

The following papers were also read: "Some Recently Collected Statistics on the Increasing Frequency of Abortion; Some Causes for the Same," by Dr. J. L. Andrews of Memphis; "Keratosis Follicularis," by Dr. G. P. Edwards of Nashville; "Bone Surgery," by Dr. R. A. Barr of Nashville; "The Physician as an Advertising Medium," by Dr. F. J. Runyon of Clarkesville.

Officers.—The following officers were elected: *President,* Dr. Cooper Holtzclaw, Chattanooga; *Vice-Presidents,* Drs. S. W. Woodyard, Greeneville, Alfred Moore, Memphis, and A. F. Richards, Sparto; *Secretary,* Dr. George H. Price, Nashville; *Treasurer,* Dr. W. C. Bilbro, Murfreesboro.

Memphis was selected as the place for holding the next annual meeting; time, second Tuesday in April, 1906.

The British Army Council has decided to discontinue the experiment of providing recruits with artificial teeth. The soldiers would not pay for their teeth, as agreed, out of their pay of a shilling a day, and when the military authorities tried to make them, they deserted, teeth and all.

Books Received.

While the MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

EIGHTEENTH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF THE STATE OF OHIO FOR YEAR ENDING DECEMBER 31, 1903. 8vo., 569 pages, paper.

A TREATISE ON PLAGUE, DEALING WITH THE HISTORICAL, EPIDEMIOLOGICAL, CLINICAL, THERAPEUTIC AND PREVENTIVE ASPECTS OF THE DISEASE. By W. J. SIMPSON, M.D., F.R.C.P., D.P.H. 4to, 466 pages, muslin. The Macmillan Company, New York. Price, $5.00.

ATONIA GASTRICA (ABDOMINAL RELAXATION). By ACHILLES ROSE, M.D., and ROBERT COLEMAN KEMP, M.D., 12mo, 215 pages, muslin, illustrated. Funk & Wagnalls Company, New York and London. Price, $1.00 net.

SALBEN UND PASTEN MIT BESONDERER BERUCKSICHTIGUNG DES MITIN. Von DR. S. JESSNER. 8vo, 37 pages. A. Stuber, Wurzburg, Germany.

ACUTE CONTAGIOUS DISEASES. By WILLIAM M. WELCH, M.D., and JAY G. SCHAMBERG, A.B., M.D. 8vo, 781 pages, muslin, illustrated. Lea Brothers & Co., Philadelphia. Price, $5.00 net.

A NURSE'S GUIDE FOR THE OPERATING ROOM. By NICHOLAS SENN, M.D., Ph.D., LL.D., C.M. 8vo, 204 pages, muslin, illustrated. W. T. Keener & Co., Chicago. Price, $1.75 net.

LARYNGEAL PHTHISIS OR TUBERCULAR LARYNGITIS. By RICHARD LAKE, F.R.C.S. Second Edition. Enlarged and Rewritten by HAROLD BARWELL, M.B., F.R.C.S. 8vo, 120 pages, muslin, illustrated. Bailliere, Tindall & Cox, London, England.

THE HISTORICAL RELATIONS OF MEDICINE AND SURGERY TO THE END OF THE SIXTEENTH CENTURY. An address delivered at the St. Louis Congress in 1904. By T. CLIFFORD ALLBUTT, M.A., M.D. 12mo, 125 pages, muslin. The Macmillan Company, New York. Price, $1.00 net.

THE BOOK OF PRESCRIPTIONS WITH AN INDEX OF DISEASES AND REMEDIES. Rewritten by E. W. LUCAS, F.I.C., F.C.S. 16mo, 366 pages, muslin. P. Blakiston's Son & Co., Philadelphia. Price, $2.00 net.

A SYSTEM OF PHYSIOLOGIC THERAPEUTICS. Vol. XI. Edited by SOLOMON SOLIS COHEN, A.M., M.D. 8vo, 388 pages, muslin, illustrated. P. Blakiston's Son & Co., Philadelphia. Complete set, $27.40.

THE DOCTOR'S RECREATION SERIES. THE DOCTOR'S WINDOW. Poems by the Doctor, for the Doctor, and About the Doctor. Edited by INA RUSSELL WARREN. 8vo, 288 pages, muslin, illustrated. The Saalfield Publishing Co., Akron, O.

DERMATOLOGISCHE HEILMITTEL. Von DR. S. JESSNER. 8mo, 96 pages. A. Stuber, Wurzburg, Germany. Price, mk. 1.50.

BEITRAGE ZUR KLINIK DER TUBERKULOSE. Herausgegeben von DR. RUDOLPH BAUER. Band III, Heft 5, 4to, pp. 331-426. A. Stuber, Wurzburg, Germany.

THE NEW KNOWLEDGE. A POPULAR ACCOUNT OF THE NEW PHYSICS AND THE NEW CHEMISTRY IN THEIR RELATION TO THE NEW THEORY OF MATTER. By ROBERT KENNEDY DUNCAN, PROFESSOR OF CHEMISTRY. 8vo, 263 pages, illustrated, muslin. A. S. Barnes & Co., New York. Price, $2.00 net.

CLINICAL TREATISES ON THE PATHOLOGY AND THERAPY OF DISORDERS OF METABOLISM AND NUTRITION. By PROFESSOR DR. CARL VON NOORDEN. Part VI. DRINK RESTRICTION (THIRST-CURES), PARTICULARLY IN OBESITY. 8vo, 86 pages, muslin. E. B. Treat & Co., New York.

PRACTICAL DIETETICS WITH SPECIAL REFERENCE TO DIET IN DISEASE. By W. GILMAN THOMPSON, M.D. Third Edition. 8vo, 846 pages, illustrated, muslin. D. Appleton & Co., New York.

ENLARGEMENT OF THE PROSTATE. By JOHN B. DEAVER, M.D., and ASTLEY PASTON COOPER ASHHURST, M.D. 8vo, 266 pages, illustrated, muslin. P. Blakiston's Son & Co., Philadelphia.

THE MEDICAL EPITOME SERIES. CLINICAL DIAGNOSIS AND URANALYSIS. By JAS. RAE ARNEILL, A.B., M.D. 12mo, 244 pages, illustrated, muslin. Lea Brothers & Co., Philadelphia. Price, $1.00 net.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending May 27, 1905:

	Cases	Deaths
Measles	888	19
Diphtheria and Croup	331	26
Scarlet Fever	184	15
Smallpox		
Chickenpox	141	
Tuberculosis	470	163
Typhoid Fever	32	4
Cerebrospinal Meningitis	76	60
Typhus Fever		
Yellow Fever		
Cholera		
Totals	2,116	287

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ending May 27, 1905:

Prevention of Otitis Media in Children.—A. Jacobi says that nasal, postnasal, and pharyngeal catarrhs should be treated before they can do harm; adenoids should be removed, enlarged tonsils resected, and hypertrophy of the mucous membrane of the nose reduced. No operation about these parts is successful unless subsequent cleanliness be enforced. Some operators neglect to avoid recurrences by not attending to that rule. One or two daily warm saline irrigations made from a nasal cup, during which the mouth should be kept slightly open—injections should never be practised—suffice for that purpose. Adenoids, when small, will get well without operation when the irrigations are gently and regularly made. Sprays or the use of droppers cannot take the place of irrigations. A spray of a 5 per cent. solution of silver nitrate through the nares once a week will work well. This application should be made several weeks in succession.—*Archives of Otology.*

A CONTRIBUTION TO HEMOPHILIA, WITH SPECIAL REFERENCE TO THE JOINT SYMPTOMS OF THE DISEASE.*

By FRANCIS P. KINNICUTT, M.D.,
NEW YORK.

PROFESSOR OF CLINICAL MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, MEDICAL DEPARTMENT, COLUMBIA UNIVERSITY.

THE case which forms the basis of this paper is told in perhaps wearisome detail to illustrate the life history of a hemophilic and to furnish data for a discussion of some of the features of the disease.

The parents and grandparents of the patient, on the paternal side, have been known by me for many years, and every facility has been at hand for the thorough investigation of the patient's ancestry.

Family History: L. P., æt. 16 years. Paternal side: The father, grandfather, great-grandfather, and great-great-grandfather were free from any evidence of hemophilic disease. The mother and her direct ancestors, on both sides, for four generations were similarly free. The grandmother on the paternal side was free from the disease, and was a first cousin of the grandfather on the same side, *i.e.* the paternal great-grandfather and maternal great-grandmother on the paternal side were brother and sister. The mother of the patient has borne four children—three boys and one girl. Three of them are alive and exempt from any evidence of hemophilia.

Personal History. His mother states that from birth the patient's skin was noticeably thin and of a delicate texture, and its color of an ivory whiteness. When he was five months old she noticed a small swelling on his leg, which was also discolored, the result, she believed at the time, of the child's knocking his leg against the crib. A little later a "blackish lump" the size of an egg suddenly appeared on his chest, without ascertainable cause, and persisted for many weeks. When two years old the patient began to suffer from severe nosebleeds, which were finally controlled with much difficulty by plugging the nostrils. From this date until five years of age he was never free for more than a few days from "black and blue spots" on various parts of the body; some of them could be traced to slight injuries; others appeared without known cause.

At five years he began to have attacks of "inflammatory rheumatism," necessitating confinement to the bed for two or three weeks in the individual attacks. They evidently were of a similar nature to those occurring later under my observation, and were probably of traumatic (hemophilic) origin, as the mother states that it was regarded as a curious phenomenon that they were usually preceded by a "bump" of the affected joints. A nosebleed at eight years was controlled only after forty-eight hours, and nearly proved fatal. A little later, following a blow on the thigh, the entire limb became greatly swollen and was apparently the seat of a very large extravasation. The following year, accompanying and subsequent to a coryza, there was slight bloody oozing from the nostrils for several weeks. In the same year the boy suffered from an attack of supposed rheumatism, involving his left hand, which became greatly swollen and discolored; the mother states that it was almost black. Dentition occurred at the normal period and was unattended with hemorrhage, with the exception of a slight oozing from the gums with the irruption of the last teeth. The patient was not vaccinated on account of the fear of bleeding. The diseases of childhood were attended with no unusual symptoms.

The patient was first seen by me in 1897. From this date until his death, seven years later, he was under my observation. My advice was sought for a recurrence of his "rheumatic" trouble. Immediately preceding this date there had been a nasal hemorrhage, entirely controlled only after nineteen days; for the first twenty-four hours it was of a very violent nature.

On examination the patient was found to be of slight physique, with well developed musculature, to possess a sensitive nervous organism and a bright intellect. The skin was of fine texture and of ivory whiteness. The skin of the face seemed unnaturally thin and transparent, the blue lines of the veins showing through their superficial covering. The examination of the different organs gave entirely negative results. The radial artery at the wrist in pulsation seemed of normal size, and the outlines of the heart showed an organ of normal dimensions. Urinalyses elicited no abnormality in the secretion. There were several skin areas on both the upper and lower extremities, some of large size, presenting various degrees of discoloration, from a nearly black to a yellowish green hue. The left knee was greatly swollen. The swelling was due to a large intra-articular effusion, with little if any into the periarthritic structures. The skin was drawn very tightly over the effusion, but was not reddened or discolored. There was acute pain in the joint, both spontaneous and on movement. The joint symptoms were believed by the mother to be of a rheumatic nature and to have followed a misstep on the stairs. In view of the previous history of the patient, the arthritic symptoms were regarded by me as of hemophiliac origin and due to intra-articular hemorrhage. The temperature was only moderately elevated (100° to 102°). The arthritic symptoms gradually disappeared and at the end of a month the joint was quite normal in appearance, and its movements were unimpaired. A similar attack occurred a year later, and on this occasion involved the right knee. In this attack there was discoloration about the joint. Subsequent to the absorption of the effusion, the function of the joint was unimpaired.

There were no further arthritic symptoms until 1900, when there was a very severe attack, again involving the right knee. The joint was greatly

*Read before the Association of American Physicians, Washington, May 16, 1905; and in part before the Practitioners' Society of New York, April 7, 1905.

swollen, with extreme tension of the overlying skin and exquisite pain, both spontaneous and on movement, requiring large doses of morphine. The skin was not reddened during the attack, but there was much subsequent discoloration about the joint. Improvement was very gradual, and an acute recurrence occurred at the end of a few weeks. There was fever throughout the earlier stage (ten days) of both attacks, the maximum temperature being 103°, with a diurnal variation between morning and night of about one and a half degrees. The patient was practically confined to his bed for eleven months, as a recurrence of the intra-articular effusion developed whenever any attempt was made to place him on his feet. During this period the other knee (the left) was slightly affected on two occasions. There was also one severe attack of hematuria.

Following the above prolonged disability and during the two subsequent years, both knee joints were on several occasions slightly affected, but no severe arthritic attack occurred until 1902. Notwithstanding the frequency and severity of the articular effusions, with their resorption the function of the joints up to this date remained unimpaired. Occasional nosebleeds during this interval were rather easily controlled by local applications of adrenalin.

In the summer of 1902, and again in the early autumn, large interstitial hemorrhages occurred into the left upper and lower extremities, in the latter instance involving the whole of the left calf. In October of the same year, shortly following the sudden occurrence of exquisite pain in the right half of the abdomen, the patient presented all the symptoms of grave hemorrhage, syncope, extreme pallor, etc., and a large interstitial hematoma speedily became palpable, occupying nearly the whole of the right abdominal wall. The hemorrhage was deep-seated, as no discoloration of the overlying skin followed. Resorption only took place after many weeks.

From 1902 until death in the summer of 1904, there occurred another severe hematuria, an effusion into the left elbow joint, and a constant succession of effusions into the capsules of both knee joints, more frequently the left. In none of the joint involvements was the skin reddened. In all the attacks pain was present, both spontaneous and on movement, and there was a rise of temperature, slight in the less severe attacks, as high as 103.5° with the larger effusions. Pari passu with the diminution in the swelling, the temperature fell and the spontaneous pain subsided. The pain on movement persisted for very considerable periods.

As a rule the effusion was wholly intracapsular. In a few of the attacks there was also a periarticular infiltration, as shown by the subsequent discoloration about the joint.

Gradually during the last two years of life the signs of a chronic arthritis of the knee joints developed. There was obvious thickening of the periarticular tissues, of the synovial membrane, fringes became palpable, and the character of the crepitus suggested partial destruction of the cartilage of the left knee joint. Finally severe contracture and a partial ankylosis of a fibrous nature, of the left knee, developed. There was very considerable atrophy, probably largely from disuse of the muscles related to the joints, especially of the left knee. The articular ends of the bones entering into the structure of the joints seemed enlarged, but as no radiographs were taken, the apparent enlargement may have been due to the thickening of the periarticular tissues.

In February, 1904, after walking on his crutches a short distance, and without any appreciable injury, the patient suddenly complained of acute pain in the abdomen, especially in the right lower half. He gradually became blanched, with fluttering pulse, and presented all the symptoms of concealed hemorrhage. When seen by Dr. Draper and Dr. Hance, he lay with knees drawn up and complained of acute pain in the lower portion of the right abdomen. The whole abdomen was distended and rigid; there was marked tenderness on palpation in the right inguinal region, with muscle resistance; no mass could be palpated. Rectal examination was negative. The urine was free from blood. Temperature 101°, pulse 120.

During the following week the symptoms continued to be of a very grave nature. The temperature fluctuated between 101° and 103°, and on the seventh day an intraabdominal tumor could be palpated in the right inguinal region. From this date improvement gradually occurred, and with diminished rigidity of the abdominal walls, the intra-abdominal mass was palpable in the lower portion of both inguinal regions and above the symphysis pubis. Resorption gradually occurred, and at the end of six weeks no distinct tumor was palpable. In the summer of 1904 the patient was taken to his home in Ohio, and in July there was a sudden recurrence of acute abdominal pain and all the symptoms of concealed hemorrhage. No blood was passed by the bowel. Syncopal attacks speedily followed and a fatal issue in twenty-four hours from the occurrence of the first symptoms.

No autopsy was obtained.

The case related possessed many points of interest: Its congenital yet not ascertainable inherited character; the frequency and severity of the arthritic attacks; the involvement of the smaller joints (the hand) on one occasion; the eventual development of permanent structural changes of the joints; and, finally, the occurrence of intra-abdominal hemorrhage and death, probably from this cause.

The hereditary nature of hemophilia was recognized as early as 1784 by Fordyce,[1] and, with continued observations, the mode of its transmission is now well recognized. Briefly it is as follows:

1. As a rule, the daughters of a bleeder father are exempt from evidence of the disease, but transmit it to their male offspring.

2. The sons are also, as a rule, exempt and do *not* transmit it to their offspring.

3. The daughter of a bleeder father may transmit the disease to a single one, to several, or to all of her offspring.

4. Where there are several daughters the capability of transmission to offspring may be confined to a single one, or all the daughters may transmit it.

5. Occasionally there is a direct transmission from father to son through several generations.

6. The disease does not appear in the issue of sons of a bleeder family, who are not themselves bleeders.

Following such laws, the transmission has been traced through many generations. In the Appleton-Swayne family of Reading, Mass., instances are present in the seventh generation.[2]

In the Clitherow family of Prescott, Lancashire, the transmission has been traced back to 1770,[3] and in two families of Tenna, Switzerland, to 1770, when they united in a common ancestor.[4]

It is reasonable to believe that a *de novo* origin of the disease is possible. The evidence in the literature to this effect is very considerable. When, as in the case related, four generations of ancestors on both sides have given no evidence of the disease, no other conclusion seems possible.

It is interesting to note that both the patient's father and grandmother on the paternal side were

sufferers from diabetes, and that the two families on the paternal side sprang from a common ancestor, four generations back.

Joint Affections—As early as 1838 Dubois[5] asserted that the intracapsular effusions in hemophilia were of a hemorrhagic nature. As his views were not based upon aspirations made during life or upon examinations after death, they were not generally accepted. In 1868 Reinert[6] published a case which he believed lent support to Dubois' statement. A year later Assmann[7] reported the finding of fluid blood on puncture of a swollen knee in a patient suffering from hemophilia. Legg,[8] in his treatise on hemophilia, published in 1872, wrote that the nature of the joint swelling was as obscure as the rest of the pathology of the disease, and that he was not acquainted with the record of any examination after death of the joints of a patient who had suffered from the swelling common in hemophilia. The generally accepted view at this period was that the arthritic symptoms of hemophalia, early recognized as characteristic of the disease, were of a rheumatic nature. Since 1872 our knowledge of the pathological anatomy of these arthropathies has gradually grown. The literature, however, is strangely scanty and is embraced in the reports of autopsies by Virchow (Lempe's case),[9] by Poncet,[10] Sir William Jenner,[11] König,[12] Sandelin,[13] Tilman,[14] of joints aspirated or opened by Ligorio,[15] in King's College Hospital,[16] (incision and autopsy, Legg's case), in the Bristol Royal Infirmary, England (aspiration, Greig Smith and Shaw's case),[17] by Cheyne,[18] by Dufour,[19] Chaves and Speroni,[20] and finally in radiographic studies by Sabrazes and Cabannes,[21] by Gocht,[22] by J. E. Shaw,[17] and by Kinnicutt.[23] The majority of these observations are on single cases.

It will be of interest before considering the conclusions reached from these observations, to review the symptomatology of the joint affections. From a careful study of the literature it is evident that the arthropathies, contrary to the generally accepted belief, may occur in earliest infancy. Pearce[24] reports a case in an infant 10 days old; Shaw[25] at 17 months; Eve[26] at 18 months; Kinnicutt at 3 years; and a number of recent observations indicate the not infrequent appearance of joint symptoms between 2 and five years of age. In the case related the arthritic attacks first occurred at 5 years. On the other hand, a marked tendency is shown to the gradual cessation of joint effusions even when they have been of unusual frequency and severity, after the completion of pubescence. The small joints as a rule escape. The knee is most often attacked; the elbow, ankle, hip, shoulder, and hand joints follow in successive frequency. The clinical manifestations vary greatly and do not seem to be wholly dependent upon the amount of the effusion. The effusion generally reaches its maximum within 24 hours, occasionally subsides very rapidly, but more frequently after 10 to 14 days, leaving an unimpaired function of the joint in many instances. The process may be repeated almost indefinitely, and often for a long period all evidence of structural joint damage is absent. There are occasional instances where complete recovery has not followed even a first attack. In one of Sadler's[27] cases the affected joint was never normal after the first attack at 3 years of age; in another of his cases permanent deformity was present at the age of 10 years.

The overlying skin may be reddened or it may preserve its normal color during the period of effusion. In two personal cases observed in the past year, repeated effusions were unaccompanied with any change in the color of the skin. In such instances the joint affection has often been mistaken for "white swelling." Discoloration not infrequently has been noted *about* the joint, indicative of an associated extracapsular hemorrhage. Pain, often of an exquisite nature, spontaneous and on movement, accompanies the swelling as a rule. In the case related it was controlled only by very large doses of morphine. In the absence of visible signs of inflammation and in the presence of extreme tension in many of the attacks in this case, the pain was believed to be due to the stretching or compression of the synovial nerve filaments. Occasionally the pain radiates from the joint, following the course of the nerves (Hamilton's case);[28] the symptom usually subsides pari passu with the resorption of the effusion; occasionally the pain disappears within a few hours, even with the persistence of the swelling (Gocht's case);[22] exceptional instances have been reported where even large effusions have been unaccompanied with pain (König's case);[12] fever usually accompanies the attack, maximum temperatures in individual cases of 100° and 103.5° being noted.

Although cases in which studies of the joint affections through incision, aspiration, and by radiographs during life, and of the structures after death, have been few and limited in the case of individual observers to single instances—with the exception of König's three cases—it may be asserted with approximate certainty that the arthritic attacks and subsequent structural changes are dependent upon a succession of intracapsular hemorrhages.

It was possible for König[12] to study the pathological processes in their various stages, and his observations have been confirmed by other observers. In the first stage there is a simple hemarthrosis; the joint is filled with fluid or coagulated blood; the synovia are injected, hyperemic, and covered with streaks—hemorrhagic clots. In the earlier attacks no further change presumably occurs. The blood is speedily absorbed and there is complete recovery. In the second stage, usually present after numerous effusions, the joint contains more or less bloody or pure serum; the synovial membrane is slightly thickened, presenting numerous thickly set brownish-stained villi or fringes; the cartilages have lost their white color and smoothness; masses of fibrin encroach upon them, showing a tendency to the formation of connective tissue, possible forerunners of adhesions. Erosions of the cartilages are also observed, especially at points where the accumulations of fibrin have occurred. The third stage is that of deformity, which in varying degree I believe to be the inevitable result of protracted hemophilic arthritis, *i. e.* frequently repeated attacks over a long period. In this stage ankylosis of varying degree, sometimes complete, usually of a fibrous character, is present; the capsule is greatly thickened; there is greater or less destruction of the cartilages; the joint cavity is filled with fibrinous deposits, more or less adherent; subluxation has been observed; and, finally, changes in the bones entering into the structure of the joint have been described.

Observations in regard to such changes are conflicting. Piollet,[29] on the authority of Sandelin, asserts that there is marked atrophy of the articular ends. Gocht's[22] radiographs apparently show that the bones are porous and less voluminous. In a protracted case with moderate ankylosis reported by Sabrazes and Cabannes,[21] radiographs show that the articular ends of the bones are seemingly intact. On the contrary Bowlby[30] observed in three cases of protracted hemophilic arthritis, during life, enlargement of the articular ends with projecting nodules of

bone; and studies of hemophilic joints in the museum of St. Bartholomew's Hospital[31] show lips of new bone at the edges of the condyles of the femur covered with nodular masses of cartilage. In the case related in the present paper, examination during life showed apparent enlargement of the articular ends. In a second case observed during the past year radiographs gave a less clear definition of the diaphyseal end of the femur related to the affected joint, the right, than of the left femur. The density of the bony tissue seemed to be increased. They also indicated the presence of a turbid intracapsular effusion, presumably blood, or of a blood clot. The radiographs were taken three weeks after the occurrence of an effusion. The arthritic attacks in this case had not been of sufficient frequency presumably to produce marked structural changes in the articular ends of the bones.

In view of these observations, a justifiable conclusion would seem to be that both hyperthrophy and atrophy of the articular bony structures occur in the late periods of hemophilic arthropathies, possibly representing different stages of the pathologic process.

Bowlby[32] regards the changes as analogous in most respects to those occurring in osteoarthritis. Goldthwait[33] believes that atrophic rather than hypertrophic changes are characteristic of true osteoarthritis (arthritis deformans).

It has been stated earlier that in patients surviving the age of pubescence, joint effusions become less frequent, or do not occur. Gocht[22] suggests that an explanation may be found in the anatomical lesions; when the joint is filled with more or less organized fibrous products, a diminution in the frequency or severity of hemorrhage is to be expected. Another reason may be found in a diminution in the hemorrhagic tendency in hemophiliacs with advancing years.

The lesions of both the second and third stages have been mistaken not infrequently for those of tuberculous arthritis and arthritis deformans respectively. Obviously a differentiation by physical signs may be often impossible.

In the second case referred to in this paper, a joint lesion was believed by orthopedic surgeons to be of a tuberculous nature until a nearly fatal surface hemorrhage (extraction of tooth) led to a more minute inquiry into the history of the patient.

König,[12] in one of his cases, opened the joint on the supposition that the disease was of a tuberculous nature; a fatal issue followed from hemorrhage. J. E. Summers[34] reports a similar case with a fatal issue. Cheyne[18] operated on a case of supposed arthritis deformans, with nearly fatal issue from hemorrhage. It was subsequently discovered that the patient was a hemophiliac, and later other joints were affected.

In the literature I have been able to find a number of instances where in families of bleeders the male members have severally exhibited joint affections without evidence of other bleeding, and surface bleeding with exemption from arthritic symptoms during the early years of life. In the history of a bleeder family reported by Sadler[27] this is clearly shown. The observation is an important one from a diagnostic standpoint.

The practical deduction from the above observations is that in joint affections bearing a resemblance to tuberculous disease, in infancy and childhood, the family history, as well as the personal history, should be studied carefully previous to operative treatment. The tuberculin test in a hemophiliac is not without danger from injury by the needle.

Before concluding the study of the joint affections, a word should be said in regard to the origin of the hemarthroses. It would seem justifiable to conclude, from the clinical histories of a large number of cases, that they may be both of spontaneous and traumatic origin, as in the case in the bleeding from other tissues of the body—in hemophiliacs.

An explanation of the frequent recurrence of hemorrhage in a single joint is suggested by the hyperplasia of the richly vascular synovia. The hyperplastic tissue once developed would permit of nipping from very slight causes.

Peritoneal hemorrhage in hemophilia must be of the rarest occurrence. In the voluminous literature which I have consulted I have been unable to find an instance, unless Lemp's case may be regarded as an example of this kind. The physical signs of an intraperitoneal tumor were apparently present during life, associated with a hematoma of the upper portion of the thigh; and at autopsy a sausage-shaped tumor was found in the iliac fossa whose composition was shown by microscopic examination to be of altered blood. In the case related in this paper the physical signs of a hemorrhage of this origin were demonstrative, and it is probable that the fatal issue was due to bleeding from a similar source. The hemorrhage may have been either spontaneous or due to some slight and unrecognized traumatism, such as a strain in the use of the patient's crutches.

It is presumable that the bleeding was from omental tissue, the blood gravitating to the most dependent portions of the abdomen.

The *treatment* of the hemorrhage in hemophilia at the best is unsatisfactory and often is ineffectual. A great variety of methods and drugs have been employed from time to time, only gradually to be discarded.

Legg,[35] in his latest publication on hemophilia, reiterates an opinion previously expressed by him[36] that "one of the most satisfactory ways of treating the bleedings is to leave them to themselves." He adds that "after they have lasted for some days and the patient is blanched and exsanguine, they cease and the patient gradually recovers." Such action, or lack of action, requires greater courage than is commonly possessed by the medical attendant.

I shall refer only to therapeutic measures which have been employed comparatively lately, and which have been regarded favorably. Drugs which act as "physiological styptics" when applied locally, and which also possess the power of increasing the coagulability of the blood when administered internally, may properly be considered as furnishing a rational therapeusis in hemophilia.

A physiological styptic, using Professor Wright's term, differs essentially in its action from that of such styptics as tannic acid, the salts of the heavy metals, alcohol, the actual cautery, etc., which produce their effect by a coagulation or a disintegrating process with possible subsequent eschar formation, or an inflammation of varying degree. The physiological styptic possesses an elective affinity for the blood itself and is inert when brought in contact with other tissues. In the lime salts these properties are found. In his investigations on "Increasing and Diminishing the Coagulability of the Blood,"[37] Wright was able to demonstrate by experiments in healthy human beings and in hemophiliacs that the coagulation time of unmixed blood could be reduced more than one-half by the addition to it of one-sixth volume of a one per cent. solution of chloride of calcium; also that a similar result could be obtained in hemophiliacs by the administration of chloride of calcium in two gramme (30 grain) doses twice daily, the effect being appreciable within a few

hours from the beginning of treatment. His investigations further showed that the continued administration of large doses of the chloride of calcium for four or five successive days was ineffectual in maintaining an increased coagulability of the blood; that its temporary discontinuance resulted in an increase in the coagulability, the maximum being reached in twenty-four hours, an effect presumably due to the elimination of an excess of the lime salt. In the subsequent forty-eight hours, the coagulation time remained at about the same level, only to diminish again one-half in the short period of eight hours after the readministration of two grammes of the chloride of calcium.

The accelerating effect of carbonic dioxide gas upon blood coagulation also suggested to Wright the employment of the gas in the treatment of hemorrhage in hemophilia.[38] In the surface bleeding the stream of gas is gently turned upon the affected surface, inhalation being unnecessary. The result of such applications in the epistaxis and buccal hemorrhages of hemophilia has been excellent. In concealed hemorrhage the *inhalation* of the gas has been used with success. The gas should be freely mixed with ordinary air, as asphyxia in *any* degree is to be avoided; an anoxyhemic condition of the blood induces a diminished coagulability.

Finally, Wright,[39] basing his therapeusis on the diminution in the white blood cells and especially the polynuclear elements in hemophilia, has employed solutions of cell nucleo-albumins for local applications. He reasons that in the deficiency of white corpuscles, the blood lacks the cellular elements which contribute the nucleo-albuminous elements to the formation of fibrin. The addition of nucleo-albumins is, therefore, essential to the formation of a sound clot.

Lachan Grant[40] has very recently reported a case of obstinate bleeding in a hemophiliac successfully treated by the internal administration of two and one-half grains of ovarian extract thrice daily. While the hemostatic action of the ovarian extract cannot be regarded as demonstrated in this instance, the theory which formed the basis of its administration is both ingenious and of interest. Good results have also been claimed recently[41] from the use of thyroid extract. The use of gelatin preparations, either locally or by subcutaneous injections, has proved as disappointing in hemophilia as in other conditions where an increased coagulability of the blood is desirable.

Among the therapeutic agents effecting the circulation of the blood through their action either upon the vessel walls or the vasomotor centers, or both, chloral hydrate and adrenal preparations have been found of distinct value as local applications in hemophilia.

To summarize present views of the most efficient therapeusis of hemophilia:

1. The internal administration of the lime salts, especially of the chloride of calcium, in doses of two grammes (30 grains) twice or thrice daily. Its continued use should be interrupted every two or three days by a period of twenty-four hours. The salt is soluble in 1.5 parts of water and is well borne by the stomach.

2. The application of solutions of the same salt, with compression, for accessible surface bleedings. Aqueous solutions of one-half per cent. are efficient. Another convenient mode of employment is in the form of a finely powdered chalk mixed with one-half per cent. solution of the calcium chloride. The less soluble lime salts, such as calcium phospate, are equally efficient for local application.

3. The use of a combination of a one-half per cent. solution of calcium chloride and one-sixth volume of a solution of nucleo-albumin, for local application. The nucleo-albumin can be obtained from aqueous extracts of various cellular tissues—testicle, thymus, thyroid, ovary, etc. If the prepared extracts are not available, a supply may be procured readily by mincing any of these tissues in a weak alkaline solution (1-500 solution carbonate of sodium) and filtering through gauze after a few minutes.

4. The application of a stream of carbonic-acid gas to the bleeding surface, in accessible hemorrhage. Its inhalation, freely mixed with ordinary air or oxygen, in concealed hemorrhage.

5. The use of four per cent. solution of cocaine hydrate for surface bleedings, and also of adrenalin (1-1000) with compression.

My personal clinical experience in the treatment of hemophilia has shown me the value of the therapeusis described, for accessible hemorrhage. At times in the history of the case related I was convinced of the efficiency of the chloride of calcium administered internally. I have been equally convinced of its value in the hemorrhages of some other constitutional diseases.

The marked increase in the coagulability of blood following its internal administration admits of demonstration, and although its effect in hemophilia unquestionably is often disappointing, possibly through ignorance of the proper mode of its employment, a general consensus of opinion at the present time gives it a high value in the treatment of the disease.

REMARKS ON THE ETIOLOGY OF FISSURE IN ANO.*

By J. RAWSON PENNINGTON, M.D.,

CHICAGO.

PROFESSOR OF RECTAL DISEASES IN THE CHICAGO POLYCLINIC, CHICAGO.

It is universally conceded that fissure in ano may be located at any point of the circumference of the anal canal. It is also conceded that in point of sequence the most frequent location of the ulcer is at or near the posterior commissure, that the next most frequent site is near the anterior commissure, and that it is very rarely found upon the sides of this passage. Mr. Goodsall, who has had a very large experience in the treatment of this disease, his found that less than one per cent. of the cases in men occur at the anterior commissure, while in females more than eight per cent. are found at that point. While all writers cite many causes of this disease and agree that the most common location of the ulcer is near the posterior median line, yet to my mind no satisfactory explanation has been given why it occurs so frequently at this point and is so rarely found in the anterior quadrant or upon the sides, or why it occurs in the anterior quadrant in less than one per cent. of the cases in males and in more than eight per cent. in females.

In considering the etiology of the disease most authors regard constipation as uniformly the exciting cause, but they fail to state why constipation has a more vicious effect on the posterior aspect of the anus than upon other parts of its circumference, or why the effect is more vicious on the anterior aspect of the anus in women than in men. Some state that the fissure is due to traumatism plus infection. If so, why does the traumatism plus infection occur with such regularity on the dorsal surface of this passage, or why does it occur in the anterior part of the anus in women eight times in one hundred cases and in men only once in one hundred cases?

In a recent text-book on rectal diseases the following statement is to be found: "If these ulcers are more common in women it is because the skin is more delicate." This author fails to state, however, why the skin of the anus in women is more delicate at the posterior commissure than at any other part of its circumference. The author of another recent work on diseases of the rectum says: "In men they are more frequently seen at or near the posterior commissure, and rarely upon the sides or anteriorly, and in women they are comparatively often seen at the anterior commissure." This author states that a severe sneeze or cough may rupture the delicate mucous membrane of the anus and cause a fissure. He fails to explain, however, why a severe sneeze or cough cracks the anterior commissure in men *rarely* and in women comparatively *often*. Another eminent writer says: "I am quite satisfied that the true explanation of the formation of the vast majority, if not all, painful fissures is as follows: During the passage of a motion one of these little valves (anal valves) is caught by some projection in the fecal mass and its lateral attachments torn; at each subsequent motion the little sore thus made is reopened and possibly extended. The repeated interference with the attempts at healing ends in the production of an ulcer, and the torn-down valve becomes swollen and edematous, constituting the so-called pile; or, as it has sometimes been called, the 'sentinel pile,' of the fissure." While all of us may have observed, at least occasionally, that if one of the crypts of Morgagni is torn down in the production of a fissure, yet we might ask this author why it happens that the anal valve situated on the dorsal surface of the anus is the one that is always caught and torn down by some projection in the fecal mass, or why it is that the projection that catches the valve is practically always located on the posterior part of the mass. Furthermore, why is it that the anterior valve is caught in less than one per cent. of cases in men and in more than eight per cent. of those in women? Why do not the valves in the anterior quadrant or on the sides of the anus become entangled in the mass more frequently? It has also been pointed out by Mr. Goodsall that the anal valves, or crypts of Morgagni, are best seen in young individuals and new-born infants, and that in adults they are not so distinct. If this author's theory as to the causation of fissure is correct, then we should expect the disease to occur more frequently in infants and young children, when the valves are more prominent, and therefore should be more readily caught and torn down by the mass of feces. On the contrary, however, he states that the disease is more frequently met with in adults, which is in conformity with the observations of all writers on this subject.

The foregoing are examples of the theories of the causation of this disease that have been universally taught and accepted. It seems to me that they are, at least in many cases, erroneous and that we should have a more comprehensive etiology, especially one furnishing better reasons why the little ulcer occurs with such frequency and regularity upon the dorsal surface of the anal canal.

It is my belief that the chief predisposing factor in the etiology of this disease is anatomic, and that the sequential location of the fissure is due to the support given to the anal canal by the sphincters and levatores ani muscles.

In order, therefore, to present the etiology from this viewpoint, it will be necessary briefly to review some of the more important embryologic and anatomic features in connection with the development of the anal canal. According to authorities on the embryology, this canal is developed from the epiblast and includes that portion of the intestinal tract extending from the true skin to the true mucous membrane, or free margin of the crypts of Morgagni. Its average length, when in a passive state, is from one to one and a half inches. Its inner tunic is a mucocutaneous structure, and it is so closely connected with the muscular wall by the fibrocellular structure that but slight movement of the one upon the other is permitted. Simultaneously with the development of the rectum from the hypoblast and mesoblast a process called the proctodeum or invagination of the epiblast is going on. (Fig. 1.) This process continues until the outer and inner, or somatic and splanchnic layers of the mesoblast are pressed together and absorbed, when the epiblast of

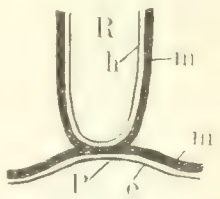

Fig. 1.—Diagrammatic. Showing the development of the rectum (R) from the hypoblastic (h) and mesoblastic (m) layers. P illustrates the beginning of the invagination of the epiblastic layer (e).

*Read before the Mississippi Valley Medical Association at Cincinnati, Ohio, October 11, 12, 13, 1904.

the proctodeum and hypoblast of the hind gut, or mesenteron, come in contact with each other, forming a thin septum, the anal membrane, between the hind gut and the proctodeum, or rectum and anal canal. (Fig. 2.) The absorption or breaking through

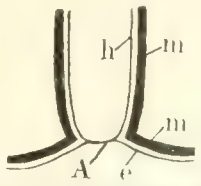

Fig. 2.—Illustrates the anal membrane (A). The outer or inner mesoblastic layers (m) having been absorbed.

of the septum completes the connection between the rectum and anus. (Fig. 3.) The failure of this ab-

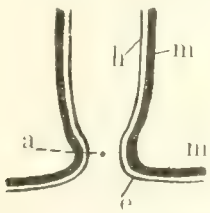

Fig. 3.—The anal membrane having been absorbed the connection between the rectum and the anal canal is established (a).

sorption causes the commonest form of imperforate anus. The anal valves, or crypts of Morgagni, appear to be the vestigial remains of this coalescence.

This canal is surrounded, supported and closed by a muscular cylinder composed of the two sphincter muscles and levatores ani. The proximal portion is surrounded by fibers from the internal sphincter and the levatores ani, and the distal or terminal portion by those of the external sphincter. Cunningham says that the internal sphincter is probably a detrusor rather than a true sphincter. The levator ani arises from the inner surface of the pubic arc, the spine of the ischium and the curved white line between these two points. Its fibers are directed downwards, backwards and inwards to be inserted into the central point of the perineum, the external sphincter around the anus, anococcygeal raphe behind the anus, and into the sides of the lower sacral

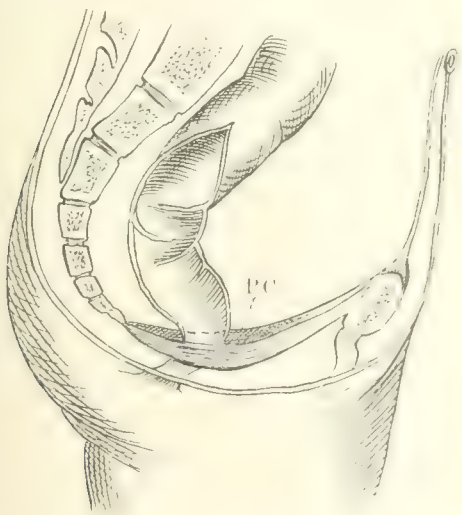

Fig. 4.—Illustrating the pubococcygeus portion (P. C.) of the levator-ani muscle.

and the coccygeal vertebræ. The anterior half of this muscle is tendinous, while the posterior half, or that attached to the coccyx, is muscular. Cunningham and others recognizes four divisions of this muscle, viz., puborectalis, pubococcygeus, iliococcygeus and ilio-sacralis. The pubococcygeus (sphincter recti portion) is the largest of these divisions. Its fibers pass backwards from the pubes and anterior portion of the white line on each side of the proximal portion, or beginning of the anal canal, and join behind this passage in a fibrous raphe, which extends back to the coccyx. (Fig. 4.) In regard to the disposition of these fibers in front of this passage, Quain says: "A few fibers of the pubo-coccygeus meet and decussate with those of the opposite muscle in front of the anus." Gerrish says: "Some of the fibers are inserted into the median raphe in front of and behind the anal canal." Cripps says: "Some of the fibers of the levatores ani, or, at any rate, some of the fascia to which they are attached, pass over the rectum blending with the fibers of the opposite side." Morris says: "Some of the fibers join the opposite muscle in a median raphe extending from the coccyx to the tendinous center of the perineum." From the foregoing it will be seen that the anterior half of this muscle is tendinous, that some of its fibers are united in a meridian raphe, which extends from the front of this passage to the tendinous center of the perineum, and that fibrous and muscular tissue crosses from side to side in front of the anus. These two muscular

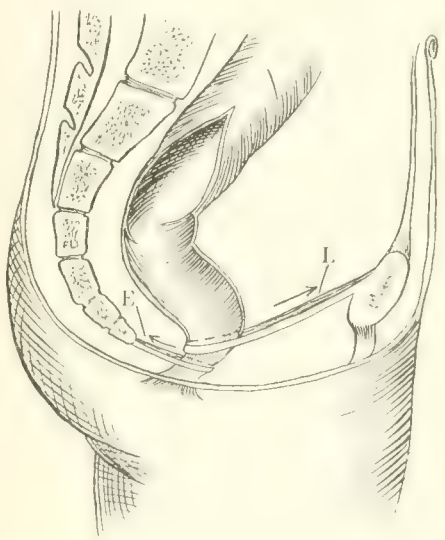

Fig. 5.—Illustrating the actions of the levatores ani (L) and the external sphincter (E) in producing the perineal flexure of the rectum.

bands then which are firmly united behind and in front of this passage are closely approximated during contraction, and aid in closing the upper part of this canal. They also lend great support to it when it is overdistended. The combined action of the levatores ani and the external sphincter produce the characteristic perineal flexure of the rectum. (Fig. 5.)

The external sphincter muscle, according to Quain, Gray and other anatomists, consists of two planes of muscle fibers, and arises from the posterior surface of the tip of the coccyx and the anococcygeal ligament. Its fibers pass forward to near the posterior commissure of the anus, where they divide into two parts and, passing forward around this aperture, join in a commissure in front of it and pass forward to the perineal body, where they are inserted, a few fibers crossing from side to side in front of and behind the anus. The distance from the coccyx, the origin of the external sphincter, to the posterior commissure of the anus, where the muscle divides, is about one and one-half inches, which is twice as great as the distance from the center of the perineal body, its insertion, to the anterior commissure, where it reunites, which is about

three-fourths of an inch. (Fig. 6.) Because of this difference in the distance between the origin and the insertion of this muscle and the center of the anal canal its fibers are more deployed posteriorly than anteriorly. Hence, when pressure is made from

Fig. 6.—External sphincter muscle. Illustrating the difference in the distance between the posterior commissure of the muscle (P. C.) and the tip of the coccyx (C), its origin and the anterior commissure of the muscle (A. C.) and the center of the perineal body (B) its point of insertion

within outwards it is obvious, since muscle fibers are more easily separated or split than broken at right angles, that (1) the weakest point in this muscle must be at or near the posterior commissure; (2) that the next weakest point is at or near the anterior commissure; (3) that this latter point is weaker in women than in men, and (4) that the lateral quadrants or sides receive the greatest support from this muscle. (Fig. 7.)

Anatomic conditions and relations almost identical with these exist between the levatores ani and the proximal portion of this canal. Hence, under similar conditions this muscle should behave in a very similar manner.

Therefore, when this canal is overdistended or placed under sufficient stress, as in the passing of a large hard fecal mass or in straining, to rupture its tissues, the tear, all things being equal, should occur first, on the dorsal surface, as it receives the least muscular support; second, on the anterior surface, as it is the next weakest point, and, third, or last, on the sides. Consequently this should be and is the sequential order in which the respective tears of the canal do occur.

Furthermore, the relative strength of these quadrants is not only true from a theoretical standpoint, but apparently from an experimental one as well. I have demonstrated, in the living, with and without the influence of anesthetics, that by gradual dilata-

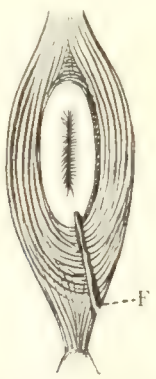

Fig. 7.—Illustrating the vicinity of the usual location of the fissure (F).

tion of the anus with a conical dilator, well oiled and of the temperature of the body, that the first break or tear occurs almost universally on the dorsal surface of the anus, and that the anterior is next to give way. The sequential order of these tears not only correspond with the weakest points in the muscular cylinder that surrounds and supports this canal, but with the statistics of the sequential location of fissure in ano.

To recapitulate: (1) The dorsal surface is the most frequent location of fissure in ano, the anterior the next and the sides the least.

(2) The dorsal surface receives the least support from the muscular cylinder that surrounds the anal canal, the anterior the next, while the sides receive the greatest.

(3) Experimentally, with and without anesthesia, a conical anal dilator, when forced into the anal canal, tears the dorsal surface first and almost universally, the anterior occasionally and the sides rarely.

(4) From the foregoing it will be seen that the sequential points of muscular weakness, experimental tears and location of fissure in ano correspond.

Columbus Memorial Building.

ON THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS.*

By G. R. POGUE, M.D.
GREELEY, COLORADO.

During the last ten or fifteen years the medical profession has taken a deeper interest in the subject of tuberculosis, thanks to those who, through personal and associated work, have endeavored to throw more light on the subject in the fields of etiology, bacteriology, pathology, therapeutics and sanitation. Others, like von Behring and Aufrecht, have, by closer investigation and original work, each apparently proven his own theory as to the modes of entrance of infection into the body and its routes of dissemination. Smith, Koch and others have performed good work in their endeavor to differentiate between human and bovine tuberculosis. Numerous other learned men in the profession throughout the civilized world have been active and diligent in their search for curative substances, in the advancement of sanitarium treatment, climatic treatment, rest and nutrition cures. These are all of the greatest importance and have supplied us with a knowledge and understanding of the disease that is invaluable both to the medical profession and the laity.

But that phase of the subject which is of the most importance not only to the physician but the patient and general public is the early recognition of the disease, and I am sorry to say it is a part of the subject that still seems to be somewhat neglected by some of the medical profession. The burden of an early diagnosis in the vast majority of all cases, no matter what the disease may be, rests on the shoulders of the general practitioner or family physician, and there are few diseases where an early diagnosis is of more importance than in tuberculosis. All authorities on tuberculosis make a statement something like this: "Tuberculosis is a curable disease and is curable in inverse ration to the length of time it has run and the extent of the lesions present." When an early diagnosis has been made in pulmonary tuberculosis is it the duty of the physician to inform the patient and his friends of the true condition of the case? I hold that a physician is criminally negligent, if, when he has discovered a case of tuberculosis, no matter how early the stage, he withholds the information and keeps the patient in ignorance, notwithstanding several arguments to the contrary.

It is impossible properly to handle such a case and

*Read before the Denver City and County Medical Society, March 7, 1905.

get the best possible results, according to our present knowledge, if the patient is not aware of the fact that he has tuberculosis. Even should he recover, in his ignorance of the condition he will be very apt to disobey instructions given and is at a loss for any sane reason why he should not do as others, with the result that he may have a recurrence. Furthermore, by making him acquainted with his condition and properly instructing him in the laws of hygiene, he does not become a menace to others or a source of infection to his family and friends. It has been stated that every case of consumption is responsible for another case and so on down the endless chain. The necessity of an early diagnosis can be seen by going over the reports of the various sanitaria, and physicians doing special work in tuberculosis. Compare the percentage of cures in the so-called first, second and third stage cases. In the first or early stages of the disease, the percentage of cures runs anywhere from 70 per cent. to 95 per cent., according to the standard of classification and the line of treatment followed, while the second and third stage cases show a markedly lower percentage of cures. That tuberculosis is a curable disease in the early stages is demonstrated outside of statistics of the living. Post-mortem examinations properly conducted show a large per cent. of adults dying of other diseases to have tubercular lesions, either active, quiescent or obsolete. Ribbert has placed the mark at 100 per cent.

It is claimed that 14 per cent. of all deaths are due to tuberculosis, or plus associated infections; therefore 86 per cent., or thereabouts, recover, or the disease has been arrested and has caused the individual little or no apparent inconvenience. The efforts of the tissues to destroy or arrest the invading microorganisms were successful in a vast majority of cases, and had the other 14 per cent. been recognized early, the proper care and treatment instituted and followed out, our death rate to-day would not be counted by the hundreds of thousands yearly. Just give this question some intelligent thought; consider the effect it would have on the spread of the disease. In the early stage before necrosis and breaking down of lung tissue takes place, there are no tubercle bacilli in the sputum, and even after the first breaking down, the foci are small and there are comparatively few bacilli thrown out with the expectoration, while an advanced case throws out its billions of bacilli daily. In this alone we would gain a great advantage in prophylaxis in properly educating the patient before he becomes a source of infection to his family or the general public.

I do not mean to say that all cases of tuberculosis pass unrecognized in the early stages, but we all know that a great number of them are either not recognized or the patient is kept in ignorance of his true condition until he has reached a stage where he is past all hope for complete recovery, when he is advised to "go West" or to try some other physician. Those of us who practice in the region of the so-called health resorts see numbers of those cases practically sent from home to die. It is not always the physician who first sees the case who is to blame. People have a horror of being told they are tuberculous, and therefore do not always accept the diagnosis. They want their own way about it, and generally visit some other physician, and if not then satisfied, go to others until they find one who will make a diagnosis to suit the patient. This is one of the greatest evils we have to overcome, as the general public as a rule have the picture of advanced consumption in their mind when we speak of tuberculosis, and to overcome this we must educate the people that tuberculosis in the early stages is curable, and to get a cure or arrest of the disease we must recognize it before necrossis and general infection takes place throughout the lung tissue. I have the histories of eighteen cases seen in the early stages of the disease, between 1892 and 1899, who went the rounds and were pronounced as suffering from anything from "stomach trouble" to "chronic malaria," and yet all of these eighteen people died of consumption in from one to five years.

There has been considerable stress laid on the findings of the microscope, and we often hear people say, "I have had my sputum examined and there are no tubercular germs in it." A positive result with the microscope is evidence of the disease, also of some necrosis, but a negative result is not evidence either way. Any one at all familiar with the pathology of tuberculosis knows that the bacilli cannot be demonstrated in the sputum until such a time as one or more foci have necrosed and their contents been discharged into an open bronchus and carried out with the bronchial secretions. Even then they may be so scarce as to escape detection, or the whole mass may be carried out at once. Microscopic examinations of the sputum, however, should never be omitted, and should be repeated at different times in all suspected cases. Even if we cannot demonstrate the specific bacillus, it will often give us valuable information in the form of elastic tissue fibers or associated infection. It is the associated infections that are responsible for the great destruction of lung tissue causing more extensive necrosis and the breaking down of the capsules that have been formed around the invading organisms, thus causing the spread of the disease to other parts of the lung or to other organs of the body, thereby transforming a case of mild tuberculosis into a case of phthisis or a case of acute miliary tuberculosis.

To make an early diagnosis in pulmonary tuberculosis it is necessary to have a knowledge of the pathology of the disease, not the gross lesions that are found in the lungs of persons dying of "consumption," but of the minute changes that take place with the first eruption of the tubercles, together with the phenomena that are produced by the action of the toxins and proteins that are elaborated during the growth of the young tubercles before a certain amount of immunity has been established by the tissues.

Mamoreck, in his work on the production of an anti-tuberculous serum, has found that toxins are produced only by the young tubercle bacilli, while the old cultures produce only tuberculins. This theory throws some light on the subject of acute tuberculosis, whether the disease be local or general. The first symptoms of acute general miliary tuberculosis are much the same as in the localized form of the disease, only greater in extent and duration. The small area of the localized disease elaborates but a small amount of toxins, and instead of overwhelming the economy, gives it an opportunity to produce an immunity, and an arrest of the disease before extensive pathological changes have taken place. It is during this first acute attack, and the interval before the next attack, that the skill of the physician is taxed to the utmost to make a diagnosis. and in the absence of enough of marked symptoms he may overlook the true condition, and attribute the malaise, chills, fever and night sweats—the result of absorption of toxins—to the other causes simply because the complete picture of consumption is lacking. Better make two mistakes in the right direction than one in the wrong. "The trouble with the doctor is, he usually defers his diagnosis until the appearance of all symptoms makes it absolutely certain that there is pulmonary tuberculosis. Instead

of this, every case in which there is reasonable ground of suspicion ought to be treated as a possible case of tuberculosis. I believe it is better to have ten men all cured, with some doubt as to how many of them really had tuberculosis, than to have five dead and five permanently damaged, and be 'dead sure' that they all suffered from the disease" (Hall).

King, in his article in the MEDICAL RECORD of January 7, 1905, gives the history of a case that is very interesting and illustrates the importance of an early diagnosis. How often have we heard this tale of woe! "If my doctor had only told me sooner —he should have known." If we do not know, we should learn to know and lift that one dark blot from the record of the medical profession. It is not new serums, antitoxins, or drugs that we require to combat tuberculosis, but an early recognition of the disease, together with the education of the laity. The latter we can never accomplish if we do not pull together and in the right direction.

My experience with early tuberculosis during the past three and one-half years has been that out of sixty-nine cases treated and properly advised, sixty-nine have had the disease arrested and are apparently cured and in good health. Seven of them have been living in the East and Middle West from one to two and a half years following their former occupations. They have learned how to live and take the proper care of themselves. Others who were apparently in a similar condition or stage of the disease and who refused to accept the diagnosis and who continued to live and act as best suited them, have become worse and some have died of tuberculosis plus accociated affections.

Just what constitutes an early case of pulmonary tuberculosis has been a subject of some discussion in the past, but at the present time it is acknowledged to be the earliest possible moment that the invading bacillus can be detected in the economy, by the history of the case, the physical signs present, the condition of the patient, and, if need be, the tuberculin test. There has been much said about the pretuberculous stage, a condition which it is impossible to describe pathologically and which really does not exist, unless we consider all those who have no tuberculous lesions to be in the pretuberculous stage. By following closely the pathology of pulmonary tuberculosis—not phthisis or consumption—we are enabled to classify the various physical signs and conditions brought about by the elaboration of the toxins and proteins, of the bacillus and the growth of the few or numerous tubercles. Every case of tuberculosis has a small beginning, and from the original lesion, after more or less time, there develops the disease that eventually (unless arrested) extends to such a degree as to overwhelm the economy, leaving in its path degeneration and death. Therefore, to make an early diagnosis in the true sense of the term, we must seek to recognize the disease during the period of the first eruption of tubercles that are great enough to produce any appreciable physical signs or cause any deviation from the normal standard we call health, and before destructive changes have taken place in the lung tissue. It is in this stage that the patient consults his physician for malaise, digestive disturbances, bronchitis, pleurisy, recurring colds, loss of appetite, decrease in weight, occasional night sweats, or irregular development of slight fever. These symptoms are more prominent in the early eruptive stages, and the physical signs more or less absent, than in the later stages even with more destructive lesions, as early in the disease the tissues have not become immunized by the presence of toxins and show a greater reaction, for the same reason that a test dose of tuberculin will give a reaction in smaller quantities in an early case than in the more chronic forms.

In pulmonary tuberculosis the lymph nodes are probably the first to become involved, whether the infection takes place through inhalation, through the tonsils and thence by way of the lymph stream or by any of the other various modes of infection; and according to the location of these infected glands and the extent of the involvement, they give rise to a set of symptoms that should always receive our careful attention. The proteins from the growing tubercle bacilli being eliminated by the bronchial mucosa causes a hacking cough and increased secretions of glairy mucus. Extensive involvement of the glands of the mediastinum may be discovered if suspected by percussion dullness, attention having been drawn to that region by the patient complaining of a dull pain behind the sternum exaggerated by coughing. There is also the slight, or at times a very pronounced, hoarseness with apparently no laryngeal involvement caused by pressure of enlarged glands or slight consolidations in the apex on the recurrent nerve often associated with excessive cough. At times the pressure may be so great as to cause paralysis of the parts supplied by the recurrent laryngeal nerve and have been classed as tuberculosis of the larynx.

Case 138 illustrates this very nicely. L. M. (female), age 29, weight 110 lbs. Seen first about December 1, 1903, and was suffering from what she had been told was "tuberculosis of the throat." Examination of the larynx revealed no signs of local tuberculous disease, but showed a paralysis of the left vocal chord and some congestion on the left side of the throat. Chest examination showed slight dullness of apex of upper lobe of left lung, with increased vocal fremitus, no moisture. She had an almost continuous harsh cough which we could not control by heroin or codein, no expectoration, and was unable to speak above a whisper. I did not see her again until about the end of February, 1904, when she contracted grip, after which she had acute necrosis of the tuberculous deposit in the apex, with cavity formation, which discharged into a bronchus. As soon as drainage was established from the cavity her voice returned to normal, the cough subsided and she required no more anodynes. The pressure on the recurrent laryngeal nerve had been relieved and its function restored.

With these symptoms before us, any or all, we should give special attention to the conditions within the chest. On examination we may recognize the extra secretion of mucus, in the form of a slight apical catarrh, by the moisture of fine crepitations, brought out by making the patient cough, following by a deep breath. If not discovered on the first examination, further examinations should be made, as the secretions are not extensive and are not always present. We cannot expect much information from palpation in the early stages, as the deposit of tubercles is not extensive enough, except they be very superficial, to cause transmission of the voice sounds. It must be remembered that the vocal fremitus is always greater over the right side, owing to the greater diameter of the right bronchus. By inspection we may learn much from the general appearance of the patient. The features are dulled, the cheeks may show a circumscribed flush, the skin is pale and apparently anemic, the veinous network shows through it, and the color changes with every exertion or emotion. Even slight exertion causes perspiration and increases quite noticeably the number of heart-beats. Further inspection of the chest may show slight depression above or even below the clavicle, apparently lack of expansion over some part

of the chest wall, especially over the seat of an old pleurisy, delayed or retarded expiration. Hemoptysis, however slight, should not be overlooked, and while examination may show no appreciable signs or deviation from the normal within the chest, the patient should be kept under observation. Very often the first symptom the patient notices is a slight or perhaps a severe hemorrhage, while he is apparently in good health, and in the absence of any of the other symptoms it is often hard to convince him that he has tuberculosis.

The thermometer is perhaps our most reliable guide in the diagnosis of early tuberculosis. It has been said that tuberculosis is an afebrile disease. This is true only in the more chronic forms when the system has established a certain amount of immunity to the toxins. In the early stages there is nearly always present in the afternoons a slight elevation above the normal, 37.2° to 38° C. This elevation may not appear every day, nor at the same hour, and it is well to make a routine practice of taking the temperature every two hours for ten days or two weeks in suspected cases.

We may also have a subnormal temperature, not only in the mornings but during the whole twenty-four hours, 35° to 36° C., or it may be subnormal in the morning with an exacerbation in the afternoon or night. Some few of my cases have had habitual subnormal temperature both A.M. and P.M. In case No. 37, the only evidence pointing to tuberculosis was a continual subnormal afternoon temperature, 34.8° to 35.8° C., and also a slight morning cough that he had for eight months. I gave him 1.5 mg. of tuberculin as a test dose, and the next day at 3 P.M. his temperature was 37.3° C. Three days later he again received 2.5 mg., and this time the temperature went up to 38.6° C., showing beyond doubt that there was some tuberculous deposit somewhere in the system, but which I was unable to locate. His recovery has apparently been complete, and he has followed his trade as carpenter and builder for two and one-half years.

In case No. 64 I found a similar temperature every day for over three weeks, the only symptom pointing to tuberculosis. A test dose of tuberculin gave a decided reaction and an elevation of 38° C. Several other patients who had a more advanced form of the disease with tubercle bacilli in the sputum, had marked subnormal temperatures.

I have used the tuberculin test in a number of suspected cases and have never seen any ill results follow its use. Neither have I seen, as has been stated by some, the release of the bacilli from their capsule so that they appeared in the sputum when they had never been found before, on careful examination. If such should happen, it is either a coincidence of rupture and test, or the reckless use of tuberculin, in large and repeated doses. In three and one-half years' experience I have seen nothing but good effects follow its use in properly selected cases. "When the disease is so slight that a diagnosis cannot be made on physical signs, nor any tubercle bacilli demonstrated in the sputum, then I believe that one, two, or three small injections of Koch's old tuberculin are absolutely free from danger. There is no recorded case where, used in the way I use this drug—1 to 10 mg.—any bad results have followed the injections, and that is the experience of Koch, Brierger, Neufeld, B. Fraenkel, Dr. Heron, and myself. Again, Professor Osler, in taking part in the discussion raised by Dr. Heron at the recent British Congress on Tuberculosis, which was chiefly concerned with the curative value of the newer forms of tuberculin, said that he regarded the old form of tuberculin as a safe and efficient diagnostic agent which he used in his routine practice at the Johns Hopkins Hospital (Latham, *Lancet,* Dec. 28, 1901, p. 1783).

In a consumptive family history the physician should see nothing more than that the patient under consideration may have had a special opportunity for infection and that people who inherit a weak constitution are more liable to infection than the offspring of vigorous parents. A phthisical family history, however, justifies a greater suspicion of infection, also a residence in a family where one or more members are afflicted with consumption regardless of relationship. For example, take case No. 152, in my record: A young woman, single, age 25, weight 127 lbs.; family history negative; both parents living and healthy. Six months previous to my seeing her she weighed 146 lbs. She gave a history of continuous good health up to three months ago, when she had a severe attack of influenza which left her with a slight morning cough, occasional night sweats, some pain in upper part of right chest, together with the other phenomena of acute tuberculosis. Three years ago she worked in a drygoods store, where one of the clerks or young men had a "cough." He always found some dark corner or out-of-the-way place in which to expectorate. At the end of six months he developed "consumption" and died. There does not seem to be any doubt as to where she contracted her disease and that the influenza infection was the cause of the acute attack which she had when I first saw her, by destroying the encapsulation of some of the foci, thereby liberating the tubercle bacilli into the surrounding tissues. It is well to remember that acute tuberculosis is very often prevalent after acute infectious diseases —like whooping cough, measles, scarlet fever, etc., especially in children—the associated affection destroying the barriers that the tissues had erected in their endeavor to destroy or arrest the invading tubercle bacillus, thereby, as stated above, liberating the germs and laying the foundation for the eruption of a new crop of tubercles. Of equal importance is the individual history in a great many cases. We may often gain valuable information in regard to repeated "catching cold," an obscure case of "malaria," so-called, "night sweats" in years gone by; a slight morning cough, or cough after retiring at night without any apparent cause; recurrent attacks of pleurisy, loss of a few pounds in weight, loss of appetite, etc. After we have taken all these things into consideration, made repeated physical examinations, used our microscope, etc., and are still unable to make a positive diagnosis, we have yet left the tuberculin test, which is reliable and devoid of danger if properly used and will practically settle the diagnosis beyond any reasonable doubt.

It is better to err on the right side than on the wrong, and, as Dr. Hall has said, "It is better that ten men should be cured and our diagnosis be in doubt in some of the cases, than that five should be dead and five permanently disabled and we be 'dead sure' that all had suffered from tuberculosis."

ENCEPHALOMENINGOCELE.*

By WILLIAM D. HAGGARD, M.D.,

NASHVILLE, TENN.

PROFESSOR OF GYNECOLOGY, MEDICAL DEPARTMENT, UNIVERSITY OF TENNESSEE; FORMERLY PROFESSOR OF GYNECOLOGY AND ABDOMINAL SURGERY, UNIVERSITY OF THE SOUTH.

THE malformations of the brain and its coverings constitute an interesting group of pathological conditions. The three chief varieties are encephalocele, meningocele, and hydrencephalocele. The first is

*Read by title before the Southern Surgical and Gynecological Association, 1904.

the most frequent and is a congenital hernia of the brain called cephalocele or "hernia cerebri." Meningocele, the least frequent, is the bulging of one or more of the membranes through a hiatus in the skull covered by the scalp. Hydrencephalocele, the most common of the large tumors, is a protrusion of brain tissue covered by skin and containing a central cystic cavity usually communicating with one of the ventricles of the brain. There may be a combination of brain and cerebrospinal fluid in the sac, encephalomeningocele, which is the rarest of all. Berger claims that the brain tissue found in meningoceles is neoplastic in character and has no physiological importance, and may therefore be disregarded from a surgical standpoint.

They are usually about the size of an orange, but vary from the size of an egg to the size of a child's head. These various cephaloceles can be situated at any part of the skull. They most commonly occur in the mesial line. Pure encephaloceles are most prone to appear in the front, meningoceles occipitally. They may protrude through any suture or through an independent opening. They occur through sphenoid and ethmoid openings, or into the mouth, nose, or orbit, and may protrude through the foramen magnum. Cases have been reported in the neck.

The etiology of these formations is not clear. Many explanations have been offered. They probably apply to different types. The various theories may be grouped under four heads: (1) Union of the brain sac with the amnion, interfering with development of bone; (2) disease of bone causing non-union or porosity, with protrusion of the brain covering through the aperture, probably coexisting with disease of the brain itself; (3) intrauturine hydrocephalous causing a bulging of the membranes as the bones come together; (4) exostoses or protuberances on the pelvis of the mother, upon which the fetal head presses, interfering with development. External injuries have been supposed to cause these malformations. Other deformities, such as cleft palate, harelip, spinabifida and clubfoot, are often associated conditions.

Encephaloceles are usually small, opaque, smooth, and not pedunculated. They have thick walls, a wide base, pulsate on violent exertion, and become enlarged during sneezing, etc., but the tension is reduced during sleep. They grow very slightly and may exist for a number of years. Pressure causes dilatation of the pupils, strabismus, vomiting, convulsions, and other symptoms of brain compression. The opening in the skull occasionally can be felt. Sometimes they are changed by retrograde processes into a meningocele, and occasionally by ossification the openings close like a fontanelle. Many of the serous cysts of the scalp have probably been encephaloceles that have lost their communication with the interior.

Meningoceles would appear to have a simpler etiology and be dependent upon a protrusion of a part of the primary cerebral vesicle, from tension or an irregular division of the brain into its different parts in utero. When of pure type they contain fluid alone and are covered by one or more of the investments of the brain. They present, therefore, fluctuation and are translucent. They are usually pedunculated. There is no pulsation and no pressure symptoms, except that the child is usually restless when lying on the tumor. They grow much larger than encephaloceles but not so large, usually, as the hydrencephaloceles. When small they are sometimes reducible. Developmental defects of the brain are commonly associated, such as hydrocephalus, porencephalus, and microcephalus.

Hydrencephalocele is oftenest occipital and contains the posterior cornua of the dilated fourth ventricle. It is pendulous and lobulated. It grows larger than any of the congenital brain tumors. Indeed, Park says: "Some of the largest occipital cephaloceles are in fact hydrencephaloceles which contain the occipital lobe of the external cerebellum, and perhaps often the quadrigemina, along with the distended posterior cornua of the lateral ventricle and the dilated fourth ventricle with the Sylvian aqueduct already distended with the contained fluid. * * * Along with the membrane which constitutes the hernial sac are also other partitions, such as the falx, tentorium, and so on, but usually more or less distorted and deformed."

The skull is usually deformed also, and the brain inside is microcephalic. Horsley has been able to determine whether or not brain was included in these tumors by the faradic current. Sometimes it can be felt. Fortunately these children rarely live long, if they do not perish during delivery. They die of marasmus or, if the membranes rupture, of septic meningitis. Children with small sincipital encephaloceles sometimes live to puberty and the mental faculties, contrary to the general rule, are alert. Out of 75 cases collected by Laurence, 6 reached adult life.

Careful examination, congenital origin, and the tenseness on crying of the smaller encephaloceles, which are the most likely ones to be mistaken, will usually serve to discriminate them from other conditions, such as wens, fatty tumors, dermoids and cephalomatoma. They have been mistaken for abscesses and opened.

About everything from simple protection by a starch bandage to surgical removal has been tried. Aseptic puncture and compression has sometimes obtained a cure. Injection with Morton's fluid has also been occasionally successful. Incision or simple ligation would hardly find favor at the present time. Operative removal is indicated in many of the meningoceles. The presence of cerebral tissue is not a contraindication except in hydrencephalus. Bergmann reports two successful cases of operation for encephalomeningocele by Schmitz of St. Petersburg. Broca said all who were operated upon before the first month died. Anandale cured one child 7 weeks old, and recently there have been reports of cases of a few days old that have been successfully operated upon. Even after a successful operation the children sometimes die of convulsions from over-distention with cerebrospinal fluid, and sometimes hyprocephalus develops. The operative mortality is very much more encouraging than formerly. Chipault collected 50 cases of operation for meningocle in the last 9 years, with only 9 deaths.

The following case is an example of a meningocele containing cerebral tissue:

Male, 4 months of age, was sent to me by Dr. F. B. Sloan of Cowan, Tenn. The child had been born in a mountain hovel of an abandoned mother, who had no attendant. A tumor as large as a goose-egg was observed on the back of the head at birth. It grew progressively, and at the age of four months measured 23 in. in its long or transverse diameter, and 17 in. in the horizontal diameter. The tumor was kidney-shaped, and together with the child had to be carried on a pillow with great care. The child weighed 6 lbs. and the tumor 5 lbs. after removal. It sprung from the occipital region. It was smooth, transparent, exquisitely fluctuating, very thin-walled, and destitute of hair, save at the pedicle and about the hilus, where there was a rather abundant, long growth. The blood-vessels could be plainly seen. The child, while small for its age, was otherwise ap-

parently normal and seemed hearty. The knee-jerks were present and sensation normal.

Handling the tumor excited crying. The sac was quite tense and did not distend upon crying. There was no pulsation. The pedicle was about the size of four fingers and very short. There was no spina-bifida or other deformity. The forehead receded markedly and gave an ape-like appearance to the face.

The case was seen by Drs. R. E. Fort, S. S. Briggs, and O. H. Wilson, who all advised operation. It was not thought at all promising, but clearly seemed the only thing to do.

Considerable difficulty was experienced in preparing the scalp and tumor for operation, as it had not been cleansed during the four months of the child's life. It was also difficult to handle the tumor. No anesthetic was given. An elastic ligature was placed around the base of the pedicle, and with large clamps above it, the tumor was amputated. In so doing it was seen that the brain tissue was cut through. The aperture in the skull was about the size of a quarter of a dollar. The bleeding vessels were tied with cat-gut, and the scalp closed over with interrupted sutures without drainage. The wound was sealed with collodion and cotton fibers.

The tumor contained a yellowish fluid, specific gravity 1.006, slightly alkaline, with considerable albumin. There was a small amount of cerebral tissue spread out over the lining at the bottom of the sac.

From a photograph, showing the relative proportion of the tumor and the head of the child.

The child showed symptoms of shock, and was given eight ounces of saline solution subcutaneously and 1-24 gr. strychnine. He reacted well from the operation, but was unable to nurse from that time on. All the functions of the body were performed normally. There were no convulsions. The pupillary and patellar reflexes were normal. There was a primary rise of temperature to 104° six hours after the operation, which receded to 99° on the second morning, and rose on the third day to 102°, but was never that high again. He exhibited a panting-like action of the tongue (polyapnea) continually.

He had been taking breast milk from a spoon satisfactorily up to this time. The wound had healed primarily and the sutures were out. He died rather unexpectedly on the ninth day. For two days previously the only conspicuous symptom was a lateral nystagmus. The temperature had not been above 100° in the four days preceding.

After death the skin flaps were separated and a small quantity of pus was found under them which the second collodion dressing had not allowed to escape. There was underneath the cerebral stump a considerable collection of cerebrospinal fluid.

IS CRANIOTOMY ON THE LIVING CHILD EVER JUSTIFIABLE.*

By I. MARX, M.D.,
NEW YORK.

The subject title of this paper resolves itself simply into a disquisition upon craniotomy versus cesarean section or symphyseotomy. The followers of the former can be designated as the conservatives, whilst the latter are embraced in the class of radicals. The interrogatory title of the article to be discussed this evening has for a long time been in the writer's mind as one befitting the thoughts of scientific obstetricians. Often and often has this subject been discussed at the bedside of the parturient woman, among the poorest as well as among the very rich, in circles where religious views and beliefs had to be weighed and carefully considered; where church affiliations and family ties were constantly swaying the poor woman, her husband and family from one determination to another. To this end, and from the uncertainty that has arisen on the part of those vitally interested, from the demoralization which has resulted from this vital uncertainty, the author has come to a finality in this question. Other things being equal, the religious question always weighing strongly, and more often than not absolutely determining the result, the writer always favors the mother as compared to the unknown fetus, when we are asked to allow the mother to suffer an increased risk to deliver her. This finality has been arrived at even in the face of the wonderful results of modern surgery. Again, years of active experience among all classes, in and out of hospitals, firmly forces the belief that only in rare cases can we consider a cesarean section on a woman many hours in labor, after manifold attempts to deliver, in the presence of a suffering fetus, as more conservative than a skillfully performed craniotomy. So far as we are concerned this standpoint relegates to the past and to the forgotten the maxim that we have so often heard: "No perforation of the living child. Away with the perforation." This much we all admit: the sphere for craniotomy is limited; but we believe its limitation must and ought to be extended, always holding that the life of the dangerously ill mother is of greater value than that of the suffering and possibly badly maimed child, which as an unborn creation is a questionable entity.

To approach the subject before us intelligently we shall first speak of the absolute contraindication for the performance of perforation. There can be no question that this condition is offered in pelves absolutely contracted either from bone approximation or through obstruction by a tumor mass. The early induction of an abortion is, if the demand is made by the vitally interested parties, our only salvation early in the pregnancy. Or, if at or near term, the elective cesarean section would be our method of choice. But too often we are confronted with such conditions and meet them, as consultants, when the suspicions of the attending physicians had not been aroused even after various and futile attempts at delivery. This dire condition can be obviated only by timely care and attention to the pelvic construction of every gravid woman. To go a step further in our exposition of the subject, we speak of: (1) The absolute indications for the operation; (2) The relative indications.

1. Absolute Indications.—There can be no question that under this category, broadminded men meet on common grounds and are practically fully agreed as how to meet certain conditions. The

*Read before the Section in Gynecology and Obstetrics of the New York Academy of Medicine.

bigoted individual as well as he who plays to the galleries, or parades his profound surgical skill with the flourish of trumpets before a large class of students, is the one who even under these conditions shouts: "The perforator is obsolete!" We do not speak of the dead child, for that is beyond the scope of the paper. But it will not be amiss to ask how often have we not all seen, as consultants, the most serious forceps or difficult forced versions done on the dead child, while the mother's soft parts were fearfully endangered, and her life almost sacrificed, when the timely use of the perforator could have ended all simply, quickly, and safely? How often has not the writer under these conditions been asked *not* to do a perforation and has it not been hinted to him to perform some difficult piece of work, as a forced version in a threatened ruptured uterus, for simple moral effect? This chapter I have added for cogent reasons, and it must appeal to you all as of the greatest importance.

The absolute indications as to (a) the fetus. Any prolonged, difficult life-saving operation on the fetus is contraindicated when that fetus is known to be suffering profoundly as shown by the well-known physical signs. After a baby has been mauled and hauled, has probably had its tender skull and brain vitally injured by the application of an array of forceps, which at times would do credit to an instrument store, its advent into this mundane sphere is better as a dead child, than as a suffering idiot. How easily could all of this have been avoided by discovering early that a malposition existed or a pelvic contraction was present. In midwifery the minor complications always give major perplexities. A contracted pelvis of the profound type is more readily discovered than a simple occipitoposterior position. Under this category, we always prefer the perforator. I can do no better than to quote from that nestor of pediatrics, Dr. Jacobi, the following: "But after all, many a baby would be better off, and the world also, if it had died during labor. There are those, and not a few, who are born asphyxiated on account of interrupted circulation, compression of the impacted head, etc., which destroys many that die in the first week of life. Those who are not so taken away may live as the result of protracted asphyxia, only to be paralytic, idiotic, or epileptic. Many times in a long life have I urged upon the practitioner to remember that every second added to the duration of asphyxia adds to the danger either to life or to an impaired human existence. All such cases prove the insufficiency of knowledge without art, or of art without knowledge, and the grave responsibility of the practical obstetrician." To all of which I solemly say, Amen! "To lose a newly-born by death, causes at least dire bereavement; to cripple his future is not rarely criminal negligence." The indication for the use of the perforator is absolute in cases of known vital deformity of the fetus, such as huge hydrocephalus and other monsters.

Absolute indications regarding (b) the mother, the wish of the parents and of the immediate family must always be satisfied. If between the operations proposed, as craniotomy and cesarean section or other cutting operation, for the purpose of saving the child, it becomes the wish of the immediate family that no risk for the mother be undertaken, it is our imperative duty to consider this an absolutely clear indication for the performance of craniotomy. The absolute indication from the maternal standpoint is presented, irrespective of the condition of the child, in all those cases in which dire and sudden accidents arise which immediately threaten the life of the mother; when the child cannot be extracted except after prolonged efforts which in themselves would not only tend to extinguish fetal life, but place an extra hazardous risk upon the mother. To perform, under these grave emergent conditions, the only operation for saving the life of the child, namely cesarean section, is out of the question, because of our utter unpreparedness. Unless a rapid forceps, version, or extraction can be done, our duty ought always be the performance of a perforation. I need only mention such grave complications as pulmonary embolus, severe accidental hemorrhage, eclampsia, etc.

Again, I wish most emphatically to impress upon the minds of this audience, the absolute necessity for the destructive operations in all cases of grave exhaustion on the part of the mother. A woman who is the victim of a prolonged fruitless labor or one who has been subjected to powerful efforts to deliver her under prolonged anesthesia, is one who would surely be annihilated by subjecting her to a cesarean section. Much rather would I *always* advocate the perforator on the living child under these conditions, than to subject the mother to the extra danger of a major operation, whose sole object would be to deliver her of a possibly living child; but at what a terrible cost? The truth of the matter, the kernel in the shell, lies not infrequently in the negligence of the attendant. Here the blame can and must be laid. Better instruction, skill, and patience on the part of the accoucheur will do more to anticipate these calamities and prevent them, than myriads of warnings uttered after these complications have occurred.

2. Relative Indications.—The skilled and technically perfect accoucheur can, by adopting various means and measures, reduce the necessity for the performance of the destructive fetal operations to a minimum. The early recognition of fetal exhaustion, the careful watch for threatening and impending maternal dissolution are all sacred and initial duties of the conscientious man. Operating too early without indications, is surely as criminal as operating too late. Timely interference, in the presence only of clear indications, of normal positions and presentations, knowing whether or not there be present disproportion between fetal head and maternal structures, are all the purest quintessence of common sense. The early recognition of vicious presenting parts and their timely correction is surely but one of the manifold duties of the physician. Means and measures at our command are numerous; to go deeply into this subject would entail words enough to fill a textbook. The application of the forceps in cases clearly indicated for forceps, the value and performance of version when there are contraindications, is again a subject which must depend on the discretion and experience of the operator. The various positions can often be utilized for ready and easy delivery, as the lateral prone, the Trendelenburg and the Walcher. Of the latter I can speak with the greatest satisfaction, for it has stood me in good stead on many occasions, whether in delivering the head in forceps cases, or in extraction by the breech in after-coming cases, supplemented by firm suprapubic pressure.

Relative indications must first and foremost depend not on us, as physicians, only, but also on the family. They are to, and must, decide the momentous question as to whether or not perforation is to be performed on the living and healthy child, in conditions of the mother, in which her life may be endangered by an operation of a major type, presumably cesarean section. To specify all these conditions would tend to make me too prolix, and I therefore refrain, for my desire is not to be elementary, for we are assembled together not as tyrōs, but as

supposed experts. But, if the question of choice be left to us as physicians, we must and ought to decide in these relative conditions in favor of an operation of a major type, when the child is in good condition or approximately so, and when the mother is not septic, and is able to stand the shock of such an operation. If there be the slightest doubt in our minds as to the outcome, we must throw our weight of scientific authority, if necessary reenforced by further counsel, in favor of a deliberate perforation on the living child. In all cases, I want to go on record as stating that unless cesarean section can be made reasonably safe, I unhesitatingly prefer a craniotomy. Cesarean section is safer in skilled hands, we all admit; but what a death rate would the operation be followed by in unskilled hands? Perforation, again, is an operation less dangerous in untrained hands, than one of a major type. The most fruitful field for the relative indication, in a personal experience, has been in cases of pelvic contraction, not absolute, principally in those of a minor type. If not recognized they form a series of dystociæ, that tests even the skill of a careful observer. These can be overcome in many women and the delivery crowned by success, by an early performance of a version, the aftercoming head being helped through the pelvis by the Walcher position, and firm suprapelvic pressure. When from an early rupture of the waters a version is impossible, the tentative use of typical or atypical forceps, again using the extension position, might be of value. The application must not be persisted in too long, nor be too powerful, for fear of doing injury to the fetus. If this be unsuccessful, the woman and child in good condition, and the patient in such environment that the outcome of an operation is reasonably certain, then and then only, would a cesarean section be allowable. But all our discussions and inclinations will in nine cases out of ten, receive their quietus by the ever-familiar phrase you all know so well, "Save my wife and destroy the child." Is this not true? Discussion among scientific men at a meeting and heart-to-heart consultations at the bedside of the parturient woman are two widely different factors. One is theory, the other practice. Let not our positions change from one to the other; and in all sincerity it is my firm conviction that perforation has a place in midwifery; and as I grow older and more experienced in my own work I feel that the field for perforation and the allied operations is widening, and that for cesarean section, safe and life saving as it may be, is narrowing for cases essentially among our private clientele and private consulting work.

GUNSHOT WOUNDS OF THE ABDOMEN.

By JOHN EGERTON CANNADAY, M.D.,

PAINT CREEK, VA.

SURGEON-IN-CHARGE, SHELTERING ARMS HOSPITAL.

Gross and Sims suggested laparotomy for gunshot and stab wounds of the peritoneal cavity. Later Bull applied this in practice. Dr. Hunter McGuire of Virginia was a pioneer contributor to the literature of this subject. In this, as in some other fields, the aggressive American surgeon long ago cast off the shackles of conservatism and blazed the trail for the more staid and cautious men of the Continent. Hence this method was first suggested, practiced, and perfected in the United States.

Not until after anesthesia made operation painless, and asepsis and antisepsis made it safe, did surgeons accomplish results worthy of the name of surgery in this field of work. With the advent of these blessings the new surgery was born. And with it came the rational treatment of peritoneal wounds.

Modern military bullets have a hard mantle of steel, copper, nickel or alloy of copper and nickel, or copper, nickel and zinc, enabling them to follow the rifling of the gun barrel. These balls weigh from 150 to 245 grns. as against the old Springfield bullet, which weighs 500 grns. The muzzle velocity varies from 1,984 to 2,329 feet per second against the Springfield's velocity of 1,300 feet per second. This hard rifle ball with a high initial velocity, rapidly revolving on its longitudinal axis, produces a neat, clean-cut perforation, which is easily sutured and heals rapidly. Unless nearly spent, this ball follows almost a direct course through the tissues. The increasing curve described by the trajectory when the force of the missile is nearly spent, causes at times the characteristic "keyhole" shaped puncture, the impact at the end of the ball on the skin at the proper angle bringing this about. The low velocity ball may produce the same sort of lesion. The dumdum or soft nose expanding bullets are liable to flatten even when striking soft tissues, producing the ghastliest of wounds.

The ordinary pistol ball passes through an unrifled barrel propelled by a powder of comparatively low explosive power. It can be deflected from its direct course by bone, cartilage, or fascia. Hence the direction of entrance is often of small indication as to its course and ultimate resting place. This ball may be flattened or distorted, producing large, ragged perforations, or the ball may change position from end to side with respect to the object it strikes, producing an oblong perforation. The intestines and other abdominal viscera being of fairly soft and yielding structure, offer but little resistance to any form of bullet.

Although the great danger of infection comes from the perforative wounds of the hollow viscera and the subsequent contamination of the peritoneal cavity, Major Louis A. LaGarde of the Army Medical Service has shown that there is danger of infection from the projectile per se, both the explosive and the ball being contaminated in from 12 to 47 per cent. of specimens examined, and that the wad and wadding are always contaminated. Also that the heat generated in firing does not in any sense destroy bacteria, and that the missile easily becomes infected en route by contact with clothing, skin, and other media. Until recently some had supposed that the combustion taking place in the gun barrel was sufficient to render the ball sterile. The ancients made use of animal, vegetable, and bacterial (in an impirical fashion) poisons in their warfare, and to this day some savage tribesmen poison their arrows and spears. After intestinal rupture peritonitis rapidly supervenes, especially so if there is much food in the intestines. In injuries below the ileocecal valve, the extravasation of intestinal contents does not as a rule take place so rapidly, but the bacterial content is proportionately greater.

The symptoms, the situation of the external wound, and the course of the bullet indicate the location and nature of the visceral lesions. Initial pain and tenderness below the umbilicus, the presence of free gas in the abdominal cavity, denote intestinal perforations. When the beginning pain and tenderness are in the epigastrium and the vomitus contains blood, we would expect wounds of the stomach. The temperature may be a little below normal, the patient may have a desire to move the bowels even after injuries to the stomach or liver. If there is any hemorrhage of note the symptoms are likely to be rapidly progressive and naturally there will be pallor, profuse perspiration, and shock. Frequently part or all of these symptoms are absent, making clear preoperative diagnosis impossible. Morphia given for

the relief of pain may mask every symptom. It is in the immediately treated cases occurring in civil life and treated by men of operative experience that brilliant results have been achieved. Here it is truly a life-saving service. In these as in some other conditions where the element of doubt as to certain diagnosis is large, an element of risk must be run. "Who dares not, never wins a race." Over conservatism has been the death knell of more than one patient. Abdominal section is often the only means by which a certain diagnosis of visceral complications may be reached at a sufficiently early hour to save life, and unless this diagnosis of bowel injury is made early, and treatment is instituted promptly, the operator had as well never been born so far as the possibilities of any benefit to the patient are concerned. To wait for tympany and peritonitis is to wait until hope is lost.

The utter impossibility of learning the extent of the damage done save by section has become proverbial; nay, even a trite truism. In these wounds occurring in civil life where the wound of entrance can be shown to have penetrated the abdominal wall, where the services of an experienced surgeon are obtainable at an early hour, laparotomy indications are imperative, as a rule, regardless of symptoms. The mortality depends for the most part upon the time of the operation and the technique of the work. In war time, when operative intervention often comes late, when the work has frequently to be done under the most adverse conditions, such men as Nicholas Senn in the Spanish-American conflict, and Sir Frederick Treves in the Anglo-Boer war, obtained results that were most disheartening and found the censervatism of inactivity to be the saner policy.

According to the dictum of Richardson, gunshot wounds of the abdomen probably having visceral involvements should be treated by laparotomy only when the operator is a surgeon of skill and experience and when the refinements of modern methods are available; under these circumstances a gunshot wound of the abdomen, when seen within two or three hours, demands immediate investigation whatever the symptoms. Gunshot wounds of the abdomen of some hours standing require exploration only when symptoms of hemorrhage or peritonitis exist. Nicholas Senn and others have found when investigating and collating mortality statistics in cases of traumatic rupture of the intestines treated by operation (bullet perforations should yield identical results) that the mortality ratio bears a direct relation to the lateness of the case. Those operated on within four hours of the receipt of the injury giving a mortality of 15.2 per cent.; five to eight hours, 44.4 per cent.; nine to twelve hours, 63.6 per cent.; later, 70.7 per cent. Visceral injuries are said by Douglas to follow 97 per cent. of gunshot wounds of the abdomen of a penetrating character.

The abdomen should be carefully inspected. The use of the probe is often misleading and harmful. Base the incision on symptoms of the patient, location of wound and apparent course of the bullet. Ordinarily a medium incision beginning just below the ensiform cartilage and extending nearly to the umbilicus will give ample opportunities for exploration and inspection of the abdominal contents. Hemorrhage requires first attention. Spleen and liver bleeding may be controlled either by gauze tamponade or deeply placed, carefully tied sutures of catgut. Mesenteric wounds are often the source of profuse bleeding. Search for intestinal injuries should be systematic, not haphazard and at random. By lifting the transverse colon the jejunum can easily be found, raised and followed in either direction. While the operator draws up and inspects each inch of bowel the assistant should be returning the inspected part to the abdomen. By careful handling and the avoidance of unnecessary exposure of the bowel to the atmosphere shock will be minimized. Hot wet gauze towels should be plentifully used over any exposed bowel. Wounds of the bowel are closed by through and through sutures of silk piercing all of the coats. The line of suture is buried by fine silk sutures superficially placed. All injuries attended to, the toilet of the peritoneal cavity should be made. It is often necessary in these cases to irrigate the abdominal cavity to remove fecal extravasations, blood, etc. In such cases the irrigator devised by Dr. Howard A. Kelley is a valuable accessory. Normal saline solution should be used and some of it left in the peritoneal cavity. As infection may come from the bullet, the wound of entrance should be carefully cleansed or excised. By reason of frequent fecal contamination and beginning or general peritonitis drainage is often needed. A light gauze wick passed through a thin rubber capot (to prevent needless adhesions) acts well; this can be removed in two or three days and a fresh strip inserted. When the peritonitis has become general, counter drainage may be made in each flank through buttonhole openings made over the ends of partially opened hemostats.

When the patient's condition will tolerate it, considerable attention should be devoted to a careful closure of the abdominal wall. I have used fine silk for the peritoneum, and a heavier grade of silk for the fascia; here the mattress suture facilitates closure by bringing larger areas together than the interrupted stitch and saving time in tying. My objection to the continuous suture for this part of the work is that by becoming loosened at any one point it may become valueless for its entire length. I consider the proper approximation and retention of the fascia as the most important prophylactic measure in the prevention of post-operative hernia. Tension sutures of silkworm gut have previously been passed through the skin, fascia, and muscle, and the skin gaps between these are closed by interrupted silk worm gut sutures, or, what is better and neater, a continuous buttonhole suture of silk is used for the entire length of the skin incision.

CUSHION DISEASES.

By JEROME D. POTTS, M.D.

ST. LOUIS, MO.

The reader must not infer from the above caption that I intend to announce the discovery of some new and startling class of diseases. Far from it, I simply wish to call the attention of the medical profession to a class, the chief etiological factor of which has been unrecognized or neglected. It is hardly to be expected that the general practitioner would take cognizance of such a factor, but when eminent specialists pass it by with slight notice, it is time that one of the lesser lights shone forth.

It is a fact, well known to anatomists, that in the construction of the human skeleton, two bony prominences with soft, elastic cushions on the extremity of each, were provided, on which the weight of the body should rest when in the sitting position. These cushioned prominences not only bear the weight of the body, but afford protection to certain soft parts situated between them. They are fixed parts of the bony pelvis, and do not change their relation to any of the organs or tissues they are designed to protect. The vertebral column, with its anteroposterior curvatures and lateral straight lines, is placed at right angles to a line drawn from one tuber ischii to the other, and, whether the body be inclined forward or

backward, they both maintain their position and bear an equal pressure.

Every man and woman of leisure, and many who are employed, must spend at least ten hours each day in the sitting posture, and more or less discomfort is experienced as a result. Modern society has decreed that these prominences need protection, and in compliance with this decree the furniture-maker and the carriage-builder have devised a multiplicity of cushions. The soft-bottomed chair is brought into service. The tubera ischii no longer perform the function for which they were provided. They sink down into the cushion, and the weight of the body is caused to rest as much upon the soft parts as upon the hard. The integument of the perineal and perianal regions, the mucous membrane of the labia, and, in relaxed conditions of the sphincters and levator and muscles, the mucous membrane of the anus, rectum, and vulva, the urethra, male and female, the prostate gland, and Cowper's glands may become diseased by violation of nature's provision.

The cushions ordinarily used are made of steel or brass springs, padded with hair or wool, and covered with some more or less impervious material. The warmth of the parts placed in contact with these is increased, the function of the sudorific follicles and sebaceous glands is stimulated to increased activity. The inability of the secretions to escape by friction or evaporation, must sooner or later result in maceration and exfoliation of the epithelial layer. Since it is a well-known fact that the epithelial layer is the protective one, it may easily be inferred that infection by some one of the ever-present pathogenic bacteria will result as soon as its integrity is broken.

Depletion of the blood vessels of the parts while under pressure must be followed by more or less congestion. Deranged nutrition ensues, and the foundation of many disease processes is laid in the injured parts.

The Allinghams, Bodenhamer, Kelsey, Mathews, Tuttle, and Gant refer to increased secretion and retention *in situ*, with maceration and exfoliation of the epithelial layer, as an etiological factor in the production of certain pathological conditions in the perianal region, but no one of them attempts to explain the cause of this increased secretion and retention. Of course, I do not presume to state that these great authors did not take cognizance of this etiological factor, but I do not think they assigned to it the importance to which it is entitled. Cushions have been used from time immemorial, and I suppose will be used for all time to come, but this is no reason why we should refuse to make known a recognized injurious result. In fact, the well nigh universal use of them makes it all the more necessary to point out the faults so they may be corrected. In my work as a specialist, I have had abundant opportunity of observing three classes of diseases, in which I regard the use of soft cushions as the chief etiological factor.

The first of these has its seat in the integument, or beneath the integument of the perineal, and perianal regions, and embraces such well-known diseases as eczema simplex, eczema marginatum, intertrigo, erythema simplex, pruritus ani, and abscesses —tugumentary and subtegumentary.

The second class has its seat in the mucous membrane, and submucous tissue, and embraces such disorders as simple urethritis, simple proctitis, anal ulcers, etc.

The third class has its origin in the blood vessels and glands, and includes such diseases as hemorrhoids, papillomata, adenomata, etc.

If the use of these cushions is the chief cause of these troubles, it may be asked, what are we going to do about it? I would answer, first, let us return to the old-fashioned hard-bottomed seat, or devise a cushion so firm that the tuberosities cannot sink down into it. This latter suggestion can be easily carried out and all the elements of beauty and comfort be conserved. The cushions can be made with firm tops and covered with some material through which evaporation can readily take place, thus instituting one of the very best forms of *preventive* treatment.

Treatment of the first class will depend upon which one of the class is present and its stage of development.

Eczema simplex in the first stage should be treated with such soothing, emollient preparations as Hebra's ung. diachyli, or a compound powder, consisting of powdered camphor, 10 grains; zinc zozoiodol, 30 grains; boric acid, 120 grains; talcum purified enough to make two ounces. The parts are to be thoroughly cleansed after each defecation, dried, and fully covered with the ointment or powder. This must be continued until all weeping surfaces are dried up. In the second stage, when we have not only weeping, but marked tendency to crust formation and itching, the treatment given for the first will be slightly modified. The crusts should be removed with warm olive or almond oil, plenty of time being taken to soften thoroughly, so that no granulations will be broken. A combination of antiseptic, astringent and protective should then be made, and a strip of soft absorbent gauze, or pledget of absorbent cotton, be placed between the buttocks. In the third stage, when the skin has become thickeined, indurated, and fissured, more drastic measures should be adopted. The parts must be cleansed with green soap, liquor detergens, or diluted caustic soda. If bleeding occurs during or after the cleansing, the parts should be rinsed with a one in four thousand solution of bichloride of mercury before applying the ointment, which should contain an astringent, antiseptic, stimulant, anodyne, and protective. Such an ointment is represented in the following compound: Resorcin, salicylic acid, 10 grains each; oil of cade, 10 drops; zinc ointment and cold cream, two drops each; mutton suet enough to make one ounce. This should be applied sufficiently often to protect the parts from exposure to the atmosphere.

Eczema marginatum, being, as is known, a disease due to the presence of the tricophyton, must be treated with a compound containing an ingredient that will destroy the germ. Such a compound may be found in the excellent formula suggested by Dr. Bulkley, of New York: Sublimed sulphur, liquid tar, each six drachms; green soap, three drachms; terra alba, three drachms; lard, one ounce. Apply to the excoriated parts. Intertrigo should be treated in the following manner: Thorough washing of the parts with soap and warm water, and, after drying, the application of some antiseptic dressing powder. If offensive ordor be present, some thymol may be added. Sometimes great benefit may be derived from the application of black wash—lotio niger—several times during the day. After it has stood for a few minutes, the parts should be dried with gauze or cotton, and covered with dusting powder. Pruritus ani is most frequently relieved by the use of the following ointment: Cocaine muriate, eight grains; antipyrin, fourteen grains; zinc oxide, two grains; cerate, five drachms. Apply to itching parts three or four times daily. Abscesses, tegumentary and subtegumentary, are to be treated with the knife. No palliative treatment of these is worthy of consideration.

Of the second class, urethritis and simple proctitis

should be treated with astringent, antiseptic, and emollient solutions. Anal and rectal ulcers by the application of stimulants and antiseptic agents. The selection of these must be left to the experience and judgment of the physician.

Of the third class, it may be said that there is practically no local treatment, save the surgical, that is worthy of serious consideration. The hemorrhoidal tumors should be removed according to some one of the approved methods. The clamp and cautery, the ligature, the injection, the excision, and the crushing methods are well established by the highest authorities, and no individual operator should feel the least timidity in adopting any one of them. My preference is given to the clamp and cautery, with the patient under full anesthesia, for the reason that the stump is left in perfectly aseptic condition when the operation is completed. Papillomata may be excised or treated with the thermocautery, electric cautery, or fuming nitric acid. The adenomata should be treated with snare, electrocautery, or the knife.

The treatment of the above classes of diseases is given in rather cursory manner, no effort being made to go into detail. For more extended information the reader is referred to some one of the many excellent treatises upon rectal and skin diseases. If the reading of this article shall convince any one of the harmfulness of soft, warm, cushioned seats, I shall be amply repaid for the writing.

518 Missouri Trust Building.

On Some Obscure Cases of Cancer of the Stomach, in Which the Main Symptoms Have Been Unconnected with That Organ.—G. Newton Pitt reports a series of seventeen cases of cancer of the stomach in which the main symptoms were not connected with that organ. These cases have occurred at Guy's Hospital during the past twenty years. Most interesting are those cases in which there is rapid extension of the growth when once the peritoneal surface has been infected. Bits of the growth tend to become loosened and may find their way in two directions. They may drop into the pelvis, where they grow. In this way intestinal obstruction may be set up, and may be the affection for which the patient first comes under observation. Perhaps more often they are sucked upward by the diaphragm and grow on its under surface. In this way they give rise to ascites, and if the growth extends upward, to pleurisy also. Valuable information may sometimes be obtained by a systematic examination of the glands above the clavicle, especially those behind the left sternomastoid muscle. The most important gland lies behind the lower two roots of the sternomastoid. When the patient coughs it is pushed up. Unfortunately it is not often involved. Growth in this gland in more than half of the cases indicates primary disease of the stomach, less often in the uterus, and exceptionally in the pancreas, liver, kidney, or ovary, etc. The writer reports three cases of matted intestines secondary to sarcoma of the stomach. The peritoneal infection caused the intestines to be matted together instead of distending the abdomen with fluid. There are among these cases twelve, that is, about 10 per cent. of all the fatal cases of cancer of the stomach in the hospital, in which the symptoms were those of malignant disease of the peritoneum. Abdominal abscesses occurred in two cases. Profound anemia was noted in two other cases. In malignant disease the diminution in the hemoglobin is not extreme. The hemoglobin index is always less than 1, and the total number of red cells is not diminished to the extent that it is in pernicious anemia. An iliac tumor appeared in one case. The writer mentions thrombosed veins in association with cancer of the stomach, but it is of such rare occurrence that it is doubtful whether it should be included in this list. He concludes by saying that such obscure cases form about 60 per cent. of the total. Some of the cases are so obscure that no more than a conjectural guess can ever be given, while in others probably a more exact diagnosis can be arrived at in the future.—*The Practitioner.*

The Removal of Foreign Bodies from the Esophagus.—Glücksmann says that it is the first object of the physician on reaching a patient who has, or is supposed to have, swallowed a foreign body is to calm the excitement both of the sufferer and of the bystanders. As soon as most of the latter have been sent away on various errands, the physician should find out, first, the nature of the foreign body; second, its supposed situation, and third, the time when it was swallowed. Having obtained this information, the pharynx should be examined with the aid of a broad tongue depressor, the soft palate, tonsils, and posterior pharyngeal wall being closely scrutinized for scratches or abrasions, and then the laryngeal mirror is to be employed for inspection of the lower pharynx and pharyngeal folds. Finally, the ocular examination is completed by a posterior rhinoscopy. If these maneuvers are all negative, the next step is digital palpation, which is always of value, and may sometimes, by the vomiting reflexes set up, cause an object deeper down to be brought up into reach. For the instrumental investigation olivary bougies are most desirable, and for extraction of small bodies the old Fergusson horsehair probang is decidedly useful, whereas the traditional coin catcher is apt to do more harm than good. The various forms of forceps are dangerous to use, and the esophagoscope should always be employed for purposes of diagnosis and removal when the body is deep seated. It must not be forgotten that the pain due to abrasions of the pharyngeal mucous membrane may cause the patient to be convinced that this is the site of impaction, whereas in reality the substance may have already reached the stomach. The family should also always be warned of the rise of temperature, or esophageal fever is likely to follow manipulations of this sort.—*Zeitschrift für diätetische und physikalische Therapie.*

A Puzzling Case.—A. B. Dalgetty calls attention to the difficulty of deciding in certain cases in the Tropics whether typhoid fever exists or not, in spite of the serum and other tests. The patient whose history he cites was a teaplained of severe pains over the lumbosacral region, tennis, the man sat down between two doors in a cool place. Two days later the writer was called to attend him. He was slightly feverish, with a furred tongue, and he complained of severe pains over the lumbo-sacral region, which were much increased by movement. For the next ten days, the condition remained unchanged. He then had a sharp attack of diarrhea which he attributed to the overdose of Epsom salts which had been given him. Five or six weeks after the beginning of the illness he began to have regular attacks of fever, coming on about six o'clock in the evening and lasting nearly all night, but remitting in the morning. He now began to complain of sharp pains under the left ribs in the splenic region. These pains sometimes shot down the thigh. The spleen could just be felt. Estivoautumnal hæmamœbæ were found in the blood. So it was clear that he was suffering from malarial fever. But sulphate of quinine which was administered to him did not destroy all of these organisms, as they were found on many subsequent occasions. There was a considerable leucocytosis. Stiffness and pain in the region of the psoas muscle continued. Examination of the blood showed a strongly marked reaction for enteric fever. The highest point of the fever throughout the whole illness was 102.2° F. After the patient had been ill nearly three months, he began to suffer from night-sweats. He was finally removed to a hospital in Calcutta, where a large peritoneal abscess in the left loin was opened. He slowly improved, and finally recovered. The writer states that even now it is not easy to decide upon the original trouble. He believes that the patient had a chronic abscess accompanied by malarial fever, and that the positive Widal reaction was fallacious.—*The Journal of Tropical Medicine.*

New York, June 10, 1905.

DIABETES MELLITUS.

THE presence of sugar in the urine is to be considered merely an indication of derangement of the bodily metabolism, which, when attended with certain other clinical phenomena, constitutes the symptom-complex—diabetes mellitus. The latter disorder has no uniform etiology, and its mechanism is, no doubt, correspondingly varied. Its morbid anatomy, likewise, is not constant, no gross lesions being at times discoverable, while at other times there is obvious disease of the central nervous system or of the pancreas. An interesting presentation of a number of phases of this important subject is given by Dr. W. Cecil Bosanquet in the Goulstonian lectures recently delivered before the Royal College of Physicians of London (*The Lancet,* April 8, 15, and 22, 1905). In summing up his views in explanation of the phenomena of diabetes and the arguments by which they were reached, he assumes that an excess of sugar in the blood, which is the condition precedent to glycosuria, may be caused by over-production of sugar in the system, or by deficient use of the same in the organism or of diminished excretion. Evidence of either of the latter processes is practically wanting, while convincing evidence exists that at one stage of diabetes, at all events, there is increased production. Over-production of sugar may depend upon some digestive irregularity, as a result of which more sugar than normal is thrown into the blood from the food, or upon the manufacture of sugar from the tissues of the body. There is sufficient evidence that both of these processes are operative in the case of diabetes, inasmuch as the output in the urine can at first be controlled by limiting the diet, while later this is not possible.

Under certain conditions sugar appears in the urine apparently as a result of absorption of additional sugar from the alimentary canal, but it is only in the presence of diabetes mellitus that there is at any time evidence of the formation of sugar from the tissue-cells of the patient. This autolytic formation of sugar is the characteristic feature of diabetes in so far as the production of sugar is concerned. It involves less of an assumption to suppose that this autolytic formation of sugar is present in cases of diabetes throughout the course of the disease than to suppose that it ensues after a time as a result of the presence in the blood of an excess of the substance, namely sugar, into which the cells finally break down. The absence of proof of the existence of this process in the early stages of the disease, when the glycosuria can be controlled by restriction of the diet, may be due to the possession by the body of a certain power of utilizing sugar in its nutritive processes so that only the excess above a definite amount appears in the urine.

There is sufficient evidence available to establish beyond the possibility of doubt the fact that there is some connection between the pancreas and diabetes. Although it has not yet been proved, yet it is becoming increasingly probable that the pancreas is diseased in all cases of diabetes mellitus. There is an accumulation of evidence showing that the function of the pancreas which is in abeyance in the presence of diabetes is normally performed by certain special groups of cells known as the islands of Langerhans, which are distinct from the ordinary cells of the gland, but which not improbably are formed from its acini. The special lesion of these islands, namely hyaline degeneration, which has been associated with diabetes by some writers, is not present in all cases of the disease, and may be found in a less developed degree in other conditions. The action of the pancreas may be exerted in the direction either of supplying a substance necessary for the assimilation of sugar by the cells of the body or of counteracting a poison that in some way leads to accumulation of sugar in the blood. There is little or no evidence in favor of the first possibility; in favor of the second are the results of experimental intoxication with phloridzin, with suprarenal extract, and with other substances, and a few inconclusive results obtained by injection of secretions derived from diabetic patients. It cannot yet be stated with any degree of certainty what tissue in the body gives rise to the sugar formed in diabetes. The theoretical possibility that sugar may be derived from fat is supported by certain observations proving that a serious disturbance of the adipose tissue exists in cases of diabetes. Further, if this hypothesis be admissible, a certain unity will be introduced into the conception of diabetes, the phenomena of which will be explicable as manifestations of a single process occurring in a single tissue. Finally, glycosuria, as opposed to diabetes, may be due to mere excess of sugar thrown into the blood from the alimentary canal beyond what the system is capable of assimilating; or it may be due to causes acting in an analogous manner to puncture of the floor of the fourth ventricle and leading to discharge of sugar by the liver from its stores of glycogen.

If the foregoing views are correct, it follows that in its earliest stage the diabetic process may constitute a predisposing rather than the actual cause of glycosuria, as the breaking down of the tissue-cells into sugar is at first not more than sufficient to saturate the sugar-assimilating powers of the system. At this stage a slight increase of saccharine food will produce glycosuria, an increase that in a normal person would not have this effect. Similarly a slight nervous shock sufficient to cause the liberation of only a comparatively small quantity of glycogen from the liver would also augment the amount of sugar present in the blood above the point at which it appears in the urine. The onset of true diabetes might thus be ascribed to a shock, when in reality it was previously existent, but unnoticed. Accordingly, in Bosanquet's opinion, diabetes mellitus can be defined as an increased internal dissociation of tissue, possibly fat, into sugar, caused by a toxic substance produced in the course of normal metabolism and normally neutralized by the pancreas.

DISINFECTION WITH FORMALDEHYDE.

Dr. Wallace Clark, Health Officer of Utica, recently read a paper on "Disinfection with Formaldehyde," before the Fourth Conference of Sanitary Officers, at Albany, which has been published in the *Medical Review of Reviews*, of March 25. Since April, 1897, formaldehyde alone has been used in Utica for disinfecting houses in which existed contagious diseases, and Dr. Clark is completely satisfied as to its efficiency. With regard to its penetrability, concerning which many bacteriologists have expressed themselves as sceptical, the author says that his experience of its use has convinced him that formaldehyde is a sufficiently penetrating disinfectant.

In the new library at Utica, the author says, there has been set aside a room for disinfecting books. The room contains about 720 cubic feet and is almost air-tight. In one corner is a heated exit flue, protected by a valve; at the other end of the room, similarly protected, is the opening of a flue which brings air from out of doors. Here the open pot method is used, the heat being supplied by a small gas stove, with stop-cock outside the room. The books are carried in on trucks with slatted shelves, back of binding up and loosely packed. The gas stove is lighted, on it is placed an iron pot, deep enough to prevent the fluid from boiling over, and in this pot ten ounces of formalin are placed. In ten minutes this solution is entirely evaporated and the gas is turned off from outside, and after several hours' exposure the inlet and outlet valves are opened. In twenty minutes the librarian can remove the trucks without discomfort. The same method is being used to disinfect the surgery in one of the Utica hospitals.

Dr. Clark's conclusions with regard to the value of formaldehyde as a disinfectant are as follows: It is a most potent disinfectant, and being of the same specific gravity as the air, will penetrate wherever air will, disinfecting at all levels of the room. It will injure nothing in the apartment but the microbes, and while a powerful germicide, it is non-poisonous to higher life, rats and cats having been submitted to the fumes with but little discomfort, and on several occasions Dr. Clark has placed a patient in an atmosphere fairly charged with this gas, for an hour or two, some slight irritation of the mucous membrane of the eye and nose alone resulting. It is inexpensive; indeed, it is by far the least expensive when we take into account the destruction and loss following the use of sulphurous acid, and also the fact that the disinfection of an ordinary residence costs less than half of the mere transportation of the goods to the steam disinfecting plant. With the new apparatus the work is very simple and convenient; there is an insignificant expenditure of time and labor, but one man being needed to do it; the fear of fire, as when sulphur is used, is avoided; the odors are quickly removed by opening the windows, and instead of arousing opposition, the process is welcomed by the householder, as nothing in the house is disturbed. Dr. Clark holds that this is the most practical method of disinfecting large buildings, such as churches, theaters, public libraries, and schoolhouses. With the greatest ease cars can be cared for, and for this purpose it was largely used last autumn in the yellow fever stricken region. Its powerful penetrating power is always taken advantage of in disinfecting the mails. This is valuable testimony in favor of formaldehyde for disinfecting purposes, and although in the opinion of some, it may seen somewhat too favorable, in the main it is doubtless correct, at least so far as the disinfection of buildings is concerned.

The Importance of Rectal Examinations in Children.

Dr. George Carpenter, in the *British Journal of Children's Diseases* for May, writes on the need of making rectal examinations in children, pointing out that bimanual examinations in pelvic and abdominal affections of childhood are of very considerable importance. He describes how such examinations should be conducted, and asserts that by following this course the whole of the pelvis can be readily explored, and abnormalities which occasion ill health and which would otherwise escape detection will be discovered with certainty. The author recites several practical examples which have come under his observation within the past few years. The fact is emphasized that there are a number of cases of localized gonorrheal peritonitis on record, the cases being incomplete by reason of the absence of a bimanual examination. Dr. Carpenter, therefore, thinks that all children suffering from a vaginal discharge should be examined per rectum as a matter of routine, especially if that discharge be gonococcal. Again, displacements of the ovaries and tubes into the inguinal and crural openings sometimes occur, and such a condition can be discovered by bimanual examination. Tuberculosis of the seminal vesicles in association with tuberculous peritonitis is occasionally discovered by a rectal examination. Bimanual examination of the abdominal cavity is, acaccording to Dr. Carpenter, of great importance in the diagnosis of affections of obscure origin. In tuberculous peritonitis this mode of examination is especially valuable. "If," says Dr. Carpenter, "on bimanual examination, there be an excess of tissue between the examining fingers, over that which can be accounted for by the abdominal parietes, there need be no hesitation in deciding in favor of tuberculous peritonitis." It is possible also sometimes to negative a diagnosis of tuberculous peritonitis by this method, and to interpret correctly the physical signs, which are apt to be misconstrued on abdominal palpation alone.

Latent or Dormant Plague.

Sir Henry A. Blake, Governor of Hong Kong in 1903, wrote a memorandum, in which he asserted that plague might be spread by animals of the most varied kind, and also concluded that there existed in Hong Kong, during the period of time intervening between June 23 and July 10, 1903, between eight thousand and nine thousand or more individuals among the native population in whom plague bacilli were present in the circulating blood in spite of the absence of all clinical symptoms of the disease. This was termed by the governor latent plague and considered an important factor in the dissemination of the disease, and one impossible to reach by the ordinary methods employed to limit the spread of and possibly to suppress plague. Drs. Maximilian Herzog, Pathologist in the Biological Laboratory of Manila, and Charles B. Hare, Assistant Bacteriologist, have been making investigations into this matter recently, and have published their results in a pamphlet issued by

the Department of the Interior, Bureau of United States Government Laboratories. The results from blood examinations made by the investigators would seem to disprove entirely the hypotheses of Governor Blake, and they attribute the continued prevalence of plague in Hong Kong to the extremely insanitary conditions which exist there. From the investigations carried on in Manila the existence of latent or dormant plague in that city can be denied. Furthermore, the statements of those who have looked into the conditions in Hong Kong, likewise appear unfavorable to the theory of Governor Blake, and they offer an explanation more in accord with what is positively known as to the nature of plague infection, and as to the spread of infectious diseases in general.

The Presence of Indoxyl in the Urine as an Index of Acute Melancholia.

A writer in the *Hospital* for April 1, refers to an article on the above subject, by Dr. A. A. D. Townsend, which appeared in the *Journal of Medical Science* for January, 1905. Acute melancholia, says the author, is always associated with an intoxication of some kind, a foul breath, furred tongue, loss of appetite, anemia in some degree, and constipation. Furthermore, these appearances are always accompanied by an excess of indoxyl in the urine. Dr. Townsend, however, finds that this excessive indoxyl excretion, while universally present in acute melancholia, is almost invariably absent in acute mania. The author's main deductions are as follows: (1) In depressed states indoxyl is excreted in excess. (2) Patients excreting indoxyl in excess exhibit symptoms and signs of toxemia. (3) In states of mental elation there is seldom any increase, the amount excreted being normal or less than normal. (4) The more severe the mental attack the greater the excess of indoxyl. (5) Mental recovery is preceded by the reduction to normal of the amount of indoxyl excreted. As to treatment of melancholia characterized by an excess of indoxyl in the urine, Dr. Townsend has found no good results from so-called intestinal antiseptics. The best treatment, in his opinion, is free purgation, and a diet composed entirely of milk. He does not claim that indoxyl is the cause of acute melancholia, but professes his ignorance as to whether it stands to the mental state in the relation of cause or effect. The annotation in the *Hospital* draws attention to the fact that no proof is forthcoming that a particular poison is the origin of any group of mental disturbances.

The Pennsylvania State Commissioner of Health.—Gov. Pennypacker has appointed Dr. Samuel G. Dixon of Philadelphia as State Commissioner of Health. The place was created by the last Legislature, and carries a salary of $10,000 and the control of a department, with an appropriation of $150,000 a year. Dr. Dixon is executive curator of the Philadelphia Academy of Natural Sciences, a trustee of the Wistar Institute of Anatomy at the University of Pennsylvania, a director of the Zoological Society of Philadelphia, and a councilor of the American Philosophic Society.

Missouri State Medical Association.—At the annual convention of this society, held in Excelsior Springs, Jefferson City was chosen as the next place of meeting. The officers elected were: *President,* Dr. Gore of Marshall; *First Vice-President,* Dr. Avery of Lincoln county; *Secretary,* Dr. C. M. Nicholson; *Treasurer,* Dr. Welsh.

News of the Week.

For the New Bellevue Hospital.—After two years of consideration, the Board of Estimate and Apportionment has finally taken action definitely committing the city to the new Bellevue Hospital project. The original plans, which involved an estimated outlay of $10,000,000, have been modified so as to reduce the expected cost of the building to $8,500,000, and the Board has authorized an appropriation of $850,000 in corporate stock to be used for the erection of two pavilions. These are to form the northernmost sections of the new hospital and are to be erected on property recently acquired by the city between Twenty-eighth and Twenty-ninth streets, First avenue and the East river. These pavilions will meet the immediate requirement for additional space in Bellevue and alleviate the overcrowded conditions which now exist, and also accommodate patients from other buildings that are to be razed to make room for the next section of the new structure.

Permission to Build a City Sanatorium Refused.—Despite the efforts of the New York City Board of Health to secure permission to locate a tuberculosis sanatorium on the top of the Shawangunk mountains at Bloomingburg, the Town Board of Mamakating decided, by a vote of 4 to 2, against the project. The Blooming burghers were possibly influenced by an anonymous postal card received by the village Board of Trade, which read as follows: "Dr. Darlington and Dr. Biggs are trying to bunco you people. Look out for them. Will colonize Tammany Hall bums between election at your place as tuberculosis cases at the expense of New York's tax. They are running a game at present." The joker dated his card from the Riverside Hospital.

Rush Medical College Will Add a Fifth Year.—It has been announced by this college that, beginning with the session of 1905-1906, a fifth year will be added to the curriculum, which for the present will be optional. The work of this year will be that of (*a*) a fellowship in one of the departments of the college, or (*b*) an interneship in the hospital under the following conditions: (1) Each student taking such work will be under the supervision of the Faculty by whom the hospital in which the interneship is taken must be approved; (2) the student must present evidence of thorough clinical work and, if possible, an exhaustive study of a selected group of clinical cases involving original work; (3) he will be required to pass a special examination at the end of the year. On the successful completion of this fifth year he will receive the degree of *Medicinæ Doctor cum laude.*

Tuberculosis in Indiana.—According to the statistics obtained by Dr. J. N. Hurty, secretary of the State Board of Health, the mortality and morbidity from pulmonary tuberculosis were much greater during 1904 than during the preceding year. The total number of deaths was 4,436, as compared with 4,035 the year before. Of this number last year 1,816 were male and 2,620 female, as compared with 1,678 male and 2,387 female the year before. Of the females 1,001 deaths were between the ages of eighteen and forty, as compared with 790 in 1903. Of the male 538 deaths were between these same ages in 1904, as compared with 425 the year before. Children to the number of 2,801 under twelve years of age were made orphans, against 2,515 in 1903.

Wisconsin Medical Bill Passed.—After much opposition, the Dinsdale bill, empowering the state board of medical examiners to refuse to grant or to revoke licenses and certificates of registration of physicians found guilty of immoral or unprofessional conduct,

was passed in the assembly by a vote of 63 to 28. The objections to the bill were based on the ground that it would give the medical board undue judicial authority.

The West Virginia State Medical Society, at the closing session of its recent meeting in Wheeling, elected the following officers: *President,* Dr. S. S. Wade, Morgantown; *First Vice-President,* Dr. P. G. Bruce, Moundsville; *Second Vice-President,* Dr. F. L. Hupp. Wheeling; *Third Vice-President,* Dr. A. S. Brimm, St. Mary's; *Secretary,* Dr. W. W. Golden, Elkins; *Treasurer,* Dr. V. T. Churchman, Charleston. Webster Springs was selected as the place for the next meeting.

Connecticut State Medical Society.—At the one hundred and thirteenth annual meeting of the society, held in Hartford, the following officers were elected: *President,* Dr. N. E. Wordin of Bridgeport; *Vice-Presidents,* Dr. F. A. Morrell of Windham, Dr. E. P. Flint of Holland; *Secretary,* Dr. W. R. Steiner of Hartford; *Treasurer,* Dr. J. H. Townsend of New Haven. Dr. George M. Sternberg of Washington and Dr. Francis Delafield of New York were elected honorary members.

New Excise Laws for Druggists.—The provisions of several changes in the excise laws which have been signed by Governor Higgins militate severely against retail druggists. The most important jeopardizes not only the druggist's liquor tax certificate, but also has his State license to do business as a pharmacist, for it provides that whenever a liquor tax certificate of a licensed druggist or pharmacist is canceled "such person shall, in addition to the other penalties prescribed by this act, forfeit the use of his license as such druggist or pharmacist for the term of one year, and be deprived of all rights and privileges thereunder during such period." The bill also provides for the revocation of a license if the holder or any of his employees be convicted of any felony whatever or of keeping a disreputable house. The other bill repeals the act of 1903 which establishes a special stamp tax permitting druggists to sell liquor in quantities of a pint or less without a physician's prescription.

Superintendent of Provident Hospital.—Miss Minnie H. Ahrens, of the Illinois Training School for Nurses, and a graduate of Clumbia University, has been appointed Superintendent of Provident Hospital, Chicago.

The Chair of Surgery at Rush Medical College.—Dr. John B. Murphy has accepted the Chair of Surgery and of Clinical surgery, Rush Medical College, but will continue to serve as attending surgeon at the Mercy Hospital, although he has severed his connections with the Northwestern University Medical School. Dr. Nicholas Senn will remain at the head of the surgical department, limiting his duties to clinical work in the fall semester, and Dr. Arthur Dean Bevan will also retain his position in the department.

Yellow Fever Still in the Isthmus.—The War Department received a dispatch last Saturday from Gov. Magoon of the Isthmian Canal Zone, stating that an American died on the Isthmus of malarial fever on May 28. He also reports two new cases of yellow fever occurring on the same date.

Dr. F. R. Dew has been nominated on the Republican ticket for coroner of Noble County, O.

Ohio State Dental Board.—Governor Herrick has reappointed the following men on this board: H. C. Brown, Columbus; J. K. Douglas, Sandusky; L. L. Barber, Toledo; Harry Barnes, Cleveland, and Stanley Smith, Cincinnati.

Ohio Medical College Commencement. — The eighty-sixth annual commencement of the Ohio Medical College took place at the Grand Opera House, Cincinnati. Thirty-three men were graduated, of whom eighteen secured hospital positions. The Faculty prize was awarded to Dr. Leslie W. Stacey, while Drs. E. O. Schwartz and F. F. Krann received honorable mention. Other prizes were awarded to Drs. Kramer, Schwartz, Heap, Zimmerman, Bertling, and Meek.

Miami Medical College Commencement. — The forty-fifth annual commencement of this college took place on June 1, at Cincinnati. Twenty-two men were graduated, twelve of whom secured hospital positions.

The Ohio Medical College Alumni Banquet occurred May 29, at Cincinnati, Dr. J. W. Rowe acting as toastmaster. Toasts were responded to by Dr. Chas. W. Dabney, Dr. Robt. Conard, Mr. Wm. Perry Rogers, and Drs. Millikan, Winn, Reed, Haines, and Rauschaff.

Ohio State Board of Health.—At a meeting held April 26, it was voted to add cerebrospinal meningitis to the list of diseases which physicians must report to the local Board of Health.

Miami Medical College Appointments.—Dr. E. W. Walker has been appointed Prof. of Principles and Practice of Surgery, Dr. O. P. Holt, Prof. of Pathology, and Dr. Frank Lamb Lecturer on Physiology. Dr. Robt. Ingram has been made Adjunct Prof. of Materia Medica and Therapeutics in the Miami Medical College, Cincinnati.

Keen Research Fellowship.—Dr. W. W. Keen, professor of surgery, has presented the sum of $5,000 to Jefferson Medical College to found a memorial to his wife and to be known as the Corinne Borden Keen Research Fellowship. The conditions of the Fellowship are that whenever the sum of $500 has been accumulated from the income it shall be awarded by the Trustees, on the recommendation of the Faculty, to a graduate of Jefferson Medical College who has been graduated not less than one nor more than ten years. The holder of the Fellowship shall spend at least one year in Europe, America, or wherever the best facilities exist in connection with the line of research that he may select after a conference with the Faculty. He will also be expected to prepare a paper embodying the results of his investigation. The first award of the Fellowship will be made in 1907 and every two years thereafter.

The George Washington University Commencement Exercises were held May 29, at Memorial Continental Hall, Washington, D. C. The Department of Medicine graduated 61, and that of Dentistry 23. The address to the graduating class in those two departments was made by Prof. Charles E. Munroe, Ph.D.

Association of Medical Librarians.—The eighth annual meeting of this association will be held in Boston, Saturday, June 10, under the presidency of Dr. James R. Chadwick of Boston. The meeting will be held in the new building of the Boston Medical Library Association. The secretary of the society is Mr. Albert T. Huntington, 1313 Bedford Avenue, Brooklyn N. Y.

The Montana State Medical Association terminated its twenty-seventh annual session, held at Butte, by elected the following officers: *President,* Dr. Donald Campbell of Butte; *Vice-Presidents,* Dr. W. W. Taylor of Kalispell, Dr. Earl Strain, and Dr. W. F. Cogswell of Livingston; *Secretary,* Dr. Grace Wilson Cahoon; *Treasurer,* Dr. I. D. Freund. Butte was again selected as the next meeting place.

The Portland (Oregon) City and County Medical Society at a recent meeting decided to give a smoker in honor of the medical visitors to the city in July. Officers for the ensuing year were elected as follows: *President,* Dr. H. W. Coe; *Vice-President,* Dr. W. H. Skenke; *Secretary,* Dr. A. D. Mackenzie; *Treasurer,* Dr. J. A. Pettit.

Obituary Notes.—Dr. Lawrence C. Swift, assistant medical examiner of Central Berkshire County, Mass., died at Pittsfield on June 1, of cerebrospinal meningitis. He was born in Geneva, N. Y., Feb. 24, 1852, and in 1878 was graduated from the College of Physicians and Surgeons in New York. Since 1887 he had lived in Pittsfield.

Dr. Thomas F. Steele died at Lebanon Hospital, in this city, on June 1, of pneumonia, at the age of thirty-five years. He was a graduate of the New York University Medical School in the class of 1888.

Dr. Thomas Xanten of St. Paul, Minn., died on May 16, of uremia, at the age of fifty-one years. He was born in Germany, but was brought to this country as a child. He was graduated from the Medical Department of the University of Iowa in the class of 1875.

Dr. Ira P. Smith of Bath, N. Y., died suddenly, on May 26, at the age of sixty-nine years. He was a graduate of the Albany Medical College in the class of 1859, and served with distinction as a regimental surgeon during the Civil War. He left a widow, a daughter, and two sons, one of whom, Dr. Douglass Smith, is a physician in Buffalo.

Dr. William K. Spiller of Bridgeport, Ala., died on May 25, at the age of sixty years. He was a graduate of the Medical Department of the University of Nashville in 1874.

Dr. Carl H. A. Kleinschmidt of Washington, D. C., died May 20. He was a graduate of the Medical Department of the University of Georgetown in the class of 1862. He was a former president of the District Medical Society and a member of the Board of Medical Examiners.

Dr. Edward Payson Drown of Malden, Mass., died, May 25, of appendicitis, at the age of thirty-nine years. He was born in Keene, N. H., and was graduated from the Harvard Medical School in 1893. He was city physician of Malden for three years, 1895-'98, past president of the Malden Medical Society, district censor of the Massachusetts Medical Society, and a member of the visiting staff of the Malden Hospital.

Dr. A. W. McClure of Mt. Pleasant, Ia., died May 20 at the age of seventy-seven years. He was born in Lebanon, O., and was graduated from the Medical College of Ohio in the class of 1853, going to Mt. Pleasant two years later. He served in the Union army as surgeon during the Civil War.

Dr. John Williams Streeter, a retired homeopathic physician of Chicago, died on June 5 at his country home in Lake Forest. He was born in Ashtabula, Ohio, in 1841, saw service during the Civil War in the Army of the Cumberland, and at the close of the war began the study of medicine at the University of Michigan. He was graduated from the Hahnemann Medical College in 1868. He was for many years president of the homeopathic staff of the Cook County Hospital. He was assistant surgeon-general, Illinois National Guard, and was a charter member of the Association of Military Surgeons of the United States. He was the author of "The Fat of the Land," a book in which the delights of farming under favorable circumstances and with abundant capital are charmingly set forth.

Correspondence.

THE AMERICAN MEDICAL ASSOCIATION; WAS IT REORGANIZED ON CORRECT PRINCIPLES, AND WILL IT, UNDER METHODS PURSUED, ACCOMPLISH WHAT IT OTHERWISE MIGHT?

To the Editor of the Medical Record:

Sir:—Organization is one of the fundamental and widely distributed laws of nature. It pervades all animal and vegetable life, and exists in every degree, from the lowest and simplest to the highest and most complex. Through its operation, stupendous forces are set in motion—forces capable of achieving wonderful and beneficent results. Man in establishing social, industrial, commercial, and political relations has sought to copy this potential law of Nature, and in proportion to the fidelity with which he has followed Nature's models has his work been characterized by order and stability, and crowned with fruitfulness. Medical men, above all others, are in position to adequately estimate the value of organization. The very nature of their studies qualifies them for such estimate. Searching into the structure of organized life, they find units, see these correlated into tissues and organs, and these in turn united into systems, all constituting one coherent, harmonious, and effective whole. Familiar with such models, medical men forcibly realize that the highest and best that can be achieved in their fields of action must come through organization upon logical and correct principles.

Having announced these general truths, which will be readily accepted, the writer will proceed to discuss the following questions:

Was the American Medical Association reorganized upon correct principles; and will it, under methods pursued, accomplish what it otherwise might?

The problems involved in the answers to these questions may be greatly simplified and clarified by first pointing out what always was, is now, and always will be the only logical, philosophical, and effective method of securing such national organization as will be fruitful, harmonious, and permanent. Inasmuch as a national body should obviously consist of a coordination of State organizations, the logical, legal, and politic method of procedure would be for a convention to be called composed of delegates appointed by State organizations for the purpose of deciding upon the principles according to which organic union could be effected, and of formulating these principles into a written constitution. After such convention had organized itself by electing officers, adopting rules for its own government, and fixing the basis of voting, it would be ready to proceed with its work.

Such an assembly would furnish a most favorable field for the display of cool and calm, and at the same time generous, judgment on the part of the delegates in an earnest effort to find common and correct ground upon which all could stand.

Among the earliest questions that would arise and demand exhaustive study and discussion would be the following:

1. What shall be the objects of national organization?
2. What shall be the representation in the national body?
3. What powers shall be conferred on the national body?

Some might insist that answers to the above questions would be easy, but such contention would reveal the most superficial comprehension of the magnitude and variety of the problems involved in the question of national medical organization.

A brief analysis of the interrogatories propounded will show of how much study and discussion they would admit. As answer to the first question—referring to objects of organization—it would be easy to write a few platitudes, such as: "To promote the science and art of medicine; to unite into one compact organization the medical profession of the United States; to foster the growth and diffusion of medical knowledge," etc.—all of which would be good enough as far as they go, but would utterly fail to touch one of the most vital and crucial questions connected with the objects of organization.

The question to which allusion is had would be: Shall the national body be so organized as to adapt it to the exercise of national public health functions? Shall it be a scientific body, pure and simple, or shall it endeavor to acquire the legal right to practically apply the teachings of science to the prevention, cure, and extinguishment of diseases?

In stating this question, the writer is aware that many will be ready to cry out, obsolete! and would attempt to justify the cry by pointing to the defunct "National Board of Health" and to the subsequent efforts made to obtain a

place for a medical officer in the Cabinet of the President of the United States.

Without stopping to point out the obvious and just causes of failure in both of these efforts, it may be confidently affirmed that whenever the medical profession of this country so organizes itself as to be in position to promptly and intelligently exercise public health functions for municipalities, counties, States, and the Nation, it will be only a question of time when such authority will be conferred. Just as a judicial system, beginning with the jurisdiction of a justice of the peace and extending up to the Supreme Court of the Nation, is organized to prevent crime and see equity done, so, a sanitary system should begin with the smallest hamlet and extend in unbroken coherency up to a Supreme Council whose jurisdiction would cover the common interest of all. Had such organization existed ten years ago, the effort to obtain recognition of a national body as a public health power might have met with quite a different fate. In other words, had good machinery for doing national public health work stood ready for practical use, unaccompanied by the injudicious and extravagant demand for a place in the Cabinet, the Nation might have shown far more willingness to utilize such machinery.

Another question in connection with a discussion of the objects of organization would be entitled to thorough study and investigation, to wit: What influence should the national body attempt to exercise over the subject of medical education?

In face of the fact that under our concentric form of government the regulation of the qualifications of practitioners of medicine belongs exclusively to the States, it would be a nice and delicate question to so provide that the national body, though possessing no power whatever in the premises, might still exercise a wholesome and judicious influence in this important field. Without pursuing this subject further, it is easy to see what a wide range for debate as to objects would stand open in a convention of the kind under discussion. Indeed, the settlement of the first question would exercise a moulding influence over the entire plan of organization. Should it be decided to so organize the national body as to adapt it to the exercise of national public health functions, then the entire plan should be made to harmonize with that idea. If, on the other hand, it should be determined not to embody that principle, corresponding modifications of the plan might be desirable. The answer to the second question would depend so largely upon the solution given to the first that we pass it by for the present, and proceed to a discussion of the third: What powers shall be conferred upon the national body?

Here, a rich and fertile field for duty and discussion would unfold. Whilst the answer to this question would depend largely upon the answers given to the two preceding ones, yet, on the general subject of powers and how derived, some basic principles may be laid down. The spontaneous generation of power is just as much an impossibility in medical organization of the kind under discussion as in physics. Power exercised must always be legitimately derived from some source where power exists, or is generated. A number of doctors, each acting for himself, may assemble and enter into an agreement that will be morally binding upon themselves, but not on others. A number of delegates representing incorporated bodies may assemble and take action that, if authorized or ratified by the appointing power, will be binding, not only upon themselves, but upon all whom they represent. The application of these axiomatic truths to the point under discussion is direct and palpable.

A number of doctors assembled from promiscuous sources and calling themselves a national body—even though acting under a charter—cannot of their own volition generate power that can be legitimately exercised over State organizations, except in reference to such matters as the State organizations represented have conceded control. It is clear, therefore, that in the hypothetical convention described, the power to create a national organization would proceed from the State organizations taking part, and would be conveyed through delegates appointed for the work. Further, the authority of such delegates would naturally and necessarily be limited to formulating a plan of organic union, and of drawing up a constitution, all of which should be reported back to the several appointing powers for ratification. As germane to the point under discussion the following extract from a report submitted by the writer as Chairman of a Board to the Medical Association of Alabama, in 1902, is here introduced:

"Without undertaking to discuss at any length the New Constitution [of the American Medical Association], or the way in which it was adopted, the Board is of the opinion that a step in the right direction has been taken, and with such changes as may, from time to time, be made, the new Constitution will be a great improvement on the old one, thus paving the way for uniting the medical organizations of all the States into one coherent national asociation. One important principle, however, must be kept in mind, namely, that the State organizations create the national association, and not the national association the state organizations. With this principle kept clearly in view it will be seen that the national association can have such powsociation, and not the national association the State organitions. But, for the common good it may become wise for the several State organizations to concede such powers to the national association as can be more uniformly and efficiently exercised by it than by the State organizations acting independently of one another. To decide what powers should be conceded and what withheld will require close study and the exercise of calm and conservative judgment."

The principles embodied in the above extract were sound when enunciated, are sound now, and always will be sound.

In order to reduce this argument to its simplest and shortest terms let us suppose that a national organization does not exist, and that it is desirable to organize one. Would not the proper method of procedure be for the State organizations to appoint delegates for the purpose, and if so appointed, would not the power proceed from the State organizations and infuse itself into whatever national body might be organized? When the three questions propounded had been thoroughly debated and definitely settled, then, and not till then, would the Convention suggested be ready to proceed with the construction of a constitution. However many principles might be formulated in advance, the embodiment of these, together with all of the connecting details, into a written instrument to serve as the organic law of the body to be created would require close study, clear judgment, nice powers of analysis, and ability to arrange principles and details in logical and sequential order. During the progress of this work a clear conception of "organizers" and "organized" should be kept in mind, in order to avoid the mistake of incorporating into the organic law of the body to be organized excessive dictatorial powers over the organizing bodies. To draw the line of demarcation between powers that belong and should forever belong to the State organizations and those that for the public good should be conceded to the national body would require a happy combination of analytical distinction and generous judgment. The time required for constructing such an instrument would necessarily be problematical, but regardless of time the delegates upon whom such an honor might devolve, realizing the magnitude of the task to be accomplished, should cheerfully, conscientiously, and unselfishly devote themselves to the work until completed.

Think of what an organic law constructed under the conditions outlined ought to be: A model! broad, comprehensive and correct in principle, ideal in details, clear and concise in language—an instrument of which all would be proud and around which every State organization would loyally, enthusiastically, and harmoniously rally. With the medical men of the United States working under such an organic law who could set a limit to what might be achieved for science and humanity?

When the work of constructing a constitution had been finished, it would remain for the document to be engrossed, verified, and signed by the delegates, which document would forever stand as the original and only constitution, of which copies could be made, but they would be copies merely.

Before adjourning, it would devolve upon the Convention to formulate an application to the general government for a charter. In making such application several points should be kept clearly in view:

1. To ask for such powers only as harmonized with the constitution agreed upon;

2. To ask that the powers be conferred on the body itself and not on a board of trustees;

3. Not to ask for any powers that under our form of government belong exclusively to the States;

4. Not to ask for the privilege of undertaking impossibilities.

It will be seen that to adjust these questions wisely and judiciously would require scarcely less analysis and study than were needed in constructing the constitution itself.

Having entirely completed their work, the delegates would report the result to their respective State organizations. If ratified by such a number of these as had been fixed in the constitution as the minimum necessary for organization, the work of the Convention would be finished; if not so ratified, a second convention would be necessary in order to harmonize differences. Naturally, the constitution would contain provision for the admission of such State organizations as were not originally included, the admission of which should be attended by formalities corresponding with the dignity of such an event.

It will be observed that the plan of procedure suggested is essentially that which was pursued more than a century ago by our forefathers in laying the founda-

tions of our present magnificent government. No better method could possibly be pursued, and if the highest wisdom in adjusting rights, prescribing lines of demarcation, and imposing duties were displayed, not only might a national medical association so constructed become as solid and permanent as is our government, but dangers growing out of differences in the interpretation of the organic law, which at one time came near disrupting the government, might be entirely avoided.

Is there anything illogical, impossible, or impolitic in the method suggested? On the other hand, is it not logical, just, and wise? In reorganizing the American Medical Association, could not this method have been carried out? Could it not be carried out now? Unquestionably. Were two or five years consumed in effecting organization upon this plan, would not the time be well spent?

Now let us contrast the method pursued in reorganizing the American Medical Association with the one suggested.

At the meeting of the Association held in 1900 provision was made for the appointment of a committee on organization, to be composed of one delegate from each State; and also for the appointment of a committee of three to revise the existing constitution. The official minutes of the meeting of 1901 tell us that the latter committee submitted a report, accompanied by a draft of a new constitution.

Without stopping to point out evident and grave irregularities that occurred in dealing with the report of the committee and without calling attention to the hasty manner in which the draft of the new constitution must have been considered by a committee to which it was referred, attention will be called to the alleged final adoption of the report of the committee of three, including as it did the proposed draft of a new constitution. On this point the minutes state: "The president then put the motion and declared the report adopted by a large majority."

Bear in mind that it was distinctly understood that in the adoption of the report the draft of the new constitution was included.

Article 11 of the old or existing constitution—then in force—reads as follows: "No amendment shall be made to any of these articles unless by unanimous consent, except at the annual meeting next subsequent to that at which such amendment has been proposed; and then only by the voice of three-fourths of all the delegates in attendance at the session when the vote is taken."

It will be seen by this article that the constitution then in force could be amended in two ways only; one, by proposing an amendment at a meeting and getting unanimous consent for its adoption; the other, by proposing an amendment at one meeting, letting it lie over to the next meeting, and then have it adopted by a three-fourths vote.

Applying this provision of the constitution to the facts as stated in the official minutes of the meeting referred to, the situation becomes clear. The draft of the proposed new constitution was first submitted at the meeting of 1901 and, as the record shows, was adopted at that meeting, not by *unanimous consent*, but by what was pronounced by the Chair "*a large majority.*" Is it not reduced to a demonstration that the constitution alleged to have been adopted at the St. Paul meeting of 1901, was never legally and constitutionally adopted, consequently was then, and is now, null and void?

When the Association convened the following year (1902) at Saratoga, the old constitution was in force, and not the draft of one that was submitted at the St. Paul meeting of the year before and was erroneously supposed to have been adopted.

The committee of three, originally appointed to revise the old constitution, and which, as has been said, submitted a revision at the St. Paul meeting of 1901, reported at the Saratoga meeting of 1902, that it "was ordered to take the new constitution and by-laws and make such verbal and other alterations as might be necessary to secure a complete, harmonious, and well-constructed instrument. In accordance with these instructions, we submit a copy of the constitution and by-laws corrected in only a few particulars."

It will be seen that it was the "new constitution" that was to undergo revision. That document being, as already shown, null and void, any revision of it must likewise be null and void.

Further, the minutes of the Saratoga meeting of 1902 do not show that the second or revised edition of the "draft of a constitution," supposed to have been adopted the year before at St. Paul, was ever read to the Association, referred to a committee, or acted upon in any way by the Association, hence the second edition stands in the same category as the first—null and void. It is clear, therefore, that when the Association adjourned at Saratoga, in 1902, it still owed allegiance to the old constitution, that instrument having never been superseded by any other.

Following in chronological order we now come to the New Orleans meeting of 1903. The minutes of that meeting show that a number of amendments to the "constitution" were either proposed or acted upon, but the citations given, in order to locate these amendments, establish beyond doubt that they referred to a printed document claiming to be a "constitution of 1902." But, as it has been shown that at the meeting of 1902 no constitution was adopted or attempted to be adopted, any amendments made at the meeting of 1903 and applying to a constitution that had no legal existence must be mere surplusage and of no effect.

As the minutes of the New Orleans meeting of 1903 failed to show that any constitution was submitted or adopted at that meeting, it inevitably follows that at the close of the meeting the old constitution was still surviving as the organic law of the Association. In the minutes of the New Orleans meeting the following appears: "On motion, the committee on organization was authorized to codify the constitution and by-laws and to correct any typographic errors contained therein."

At the Atlantic City meeting of 1904 this committee submitted a document with the following title: "Proposed Revised Constitution and By-laws of the American Medical Association. Submitted for adoption by the House of Delegates of the American Medical Association, June, 1904, by Committee appointed May, 1903." This, therefore, was a new document, a proposed revision, which, as its title indicates, had never before been submitted to the Association.

As the old constitution was in force, any proposed revision of the "constitution" would be legally construed to mean the existing constitution, therefore, any revision of it must be done in accordance with the provision therein applying to amendments. The minutes further tell us that this proposed revision of the constitution and by-laws was submitted to the Association and referred to a new and larger committee, the number not being stated. The following day this committee made its report, which, after having been amended in one point, was adopted. The minutes fail to show that this proposed revision or any part of it was ever read to the Association. They also fail to show that when the motion to adopt was put, the writer raised the point of order that it was in open violation of an express provision of what was *then* believed to be the existing constitution, to adopt a revision of it under the conditions prevailing. The point of order being over-ruled by the president, the motion to adopt was put and carried.

Tried either by the provision in the old and real constitution, or by that in what was believed to be the existing constitution, prescribing the way in which amendments must be made, this action was illegal and void. Under the old and real constitution, unanimous consent would have been necessary to adopt the proposed revision. The minutes do not show that unanimous consent was obtained. Under what was believed to be the existing constitution, a three-fourths vote of all the members composing the House of Delegates would have been necessary for adoption. The minutes do not show that a three-fourths vote for adoption was obtained.

The conclusion cannot, therefore, be escaped that the proposed revision of the constitution as submitted at the Atlantic City meeting of 1904 was not legally or constitutionally adopted. We are inevitably driven to the conclusion, therefore, that the document which now purports to be the constitution of the American Medical Association is of no validity whatever—in other words, is null and void.

When the Atlantic City meeting adjourned, the old constitution still stood as the organic law of the Association, and will so stand when it convenes in Portland at the forthcoming meeting.

This review of the work of the Association in trying to adopt a new constitution has necessarily been somewhat tedious, but it has revealed with the force of a syllogism the actual situation, namely, that in respect to a constitution the Association stands now just where it did five years ago, when it convened in St. Paul, and undertook the work of reconstruction and of revising the constitution.

The history of these five years should teach a valuable lesson, and the importance of always doing things in a thoroughly constitutional, orderly, and parliamentary way.

In view of the fact that the Association is growing, that its revenues are increasing, that it has become a property owner, that it holds deeds, and may have occasion to make deeds, it would be idle, yea, criminal, to ignore the situation.

If the organization stands upon a false foundation it is far wiser to boldly face it and proceed promptly to correct the errors of the past. This can be done, and if all will work earnestly and harmoniously to achieve that end, it *will* be done.

Montgomery, Ala. W. H. Sanders, M.D.

OUR LONDON LETTER.

(From Our Special Correspondent.)

MEDICAL SOCIETY'S CONVERSAZIONE AND ORATION—ROYAL SOCIETY—CONSUMPTION—REGISTRATION AND NURSES—INFLUENZA.

LONDON, May 19, 1905.

THE annual conversazione of the Medical Society took place on Monday, when the Fothergillian gold medal was presented to Sir F. Treves by the president, Mr. John Langton.

The oration was delivered by Mr. Henry Morris, who seized the opportunity of considering a subject which has excited a good deal of attention of late, viz., the financial relations of our hospitals and medical schools. I have kept you informed of the discussions that have ensued on this matter and of the action of the King's Hospital Fund. Mr. Morris maintained that there were good reasons why a portion of a hospital's income should be devoted to the medical school connected with it. The sick poor, he said, were greatly benefited by the training of our students—and that not merely within the walls of the hospitals, but to a much greater extent outside. The schools have been declared by Sir Arthur Rucker to be an integral part of the necessary machinery for helping the sick poor. But it has been officially announced that after the present year the King's Fund will not contribute to those hospitals which give towards their schools any of the hospital subscriptions. Mr. Morris hoped the hospitals concerned would at once establish separate funds for their schools. At the London Hospital a discretionary fund has already been opened, to which in the first week of its existence the sum transferred by the hospital supporters was more than double the amount ever contributed to the school from the hospital funds. No doubt a similar spirit will be shown by subscribers to other hospitals as soon as separate school funds are established.

The Royal Society's first soirée for the season was held on Wednesday evening, when the exhibits attracted great attention and were representative of the work of the year, especially in physical science. Thus, the effects of radium emanations on glass were shown to be similar to those of sunlight but to be produced in a fraction of the time, a few rays of radium equalling half a century of sunlight. Fleming's cymometer for the measurement of Hertzian waves, Sir W. Ramsay's actinium, and Sir O. Lodge's mercury vapor valves were also shown. Of the more medical exhibits, I may mention the so-called Plimmer's bodies.

The Lord Mayor presided on Wednesday at a meeting at the Mansion House in support of an appeal on behalf of the society for preventing consumption. Sir W. Broadbent and Sir J. Crichton-Browne were among the speakers. The former hoped the Metropolitan Asylum Board would take up the subject as it had been asked to do. £10,000 is asked for, but many are exceedingly doubtful of the plans proposed and not a few altogether discountenance them.

Sir V. Horsley yesterday gave evidence before a select committee of the House of Commons in favor of the registration of nurses and an examination by a statutory authority. He said it would be useless to register training institutions, as that would only perpetuate the present system which is unsatisfactory, as it leaves the control of the nurses with the private persons—the heads of nursing establishments. He would make it illegal to nurse for gain unless registered. The probable effect of this may be seen in the protection afforded to doctors by registration!

A discussion on influenza extending over two evenings would naturally elicit some practical clinical observations. This was the case in the recent debate arranged by the Hunterian Society, although theoretical considerations were also in evidence. Prof. Clifford Allbutt opened the discussion, a fact which drew an expectant audience. He said the disease had been known fairly well since the Twelfth Century, and he traced the progress through the world of the 1889-90 epidemic. Contagion is now generally accepted, but this was not so in 1890, when, as a commissioner in lunacy, he was able to notice its incidence in asylums. He then observed that the staff (medical and domestic) and visitors—people who went into the outer world—were attacked at the rate of about 50 per cent., but on the inmates—who did not go out—the incidence was slight. Dr. Allbutt thinks the contagion is in the sputum and springs from the respiratory passages, and unless a patient has some affection of these passages he is not contagious. He laid great stress on the suddenness of attack as a diagnostic point, especially in differentiation from typhoid. As to treatment, he emphasized the injunction that patience ought to do what they never will, viz., go to bed at once and stay there till the acute stage is over. During the long convalescence he advised a non-toxic diet, viz., milk, custards, and no meat. Dr. Allbutt reiterated his well-known opinion on angina pectoris; he holds the seat of pain to be not in the heart, but in the first part of the aorta. He mentioned an interesting case and dwelt on the complications and sequels of influenza. He gave an impressive warning against the administration of chloroform for some time after influenza.

Dr. Franklin Parsons followed with a paper on the Epidemiology of Influenza. In the course of it he showed a diagram of the course of the disease, so far as it is recorded in the mortality tables since the causes of death were tabulated by the Registrar General in 1847. Another diagram showed the course of the epidemic in London, 1889-90.

Dr. Bulloch discussed the bacteriology of the disease and admitted that no new facts have been added to Pfeiffer's discovery of 1892. A practical point as to his bacillus is its parasitic nature, rendering cultivation difficult. It is very susceptible to drying—which is against the idea of its being carried far in the air. The extreme temperatures at which it grows are 27° C. and 42° C., so that in temperate climates it does not multiply outside the body. It must in most cases be spread from man to man. Of late years the bacillus has become less frequently met with, although epidemics of catarrh called influenza are not less prevalent. Dr. Bulloch holds that clinically influenza is not one disease but several—caused by different microbes, among them micrococcus catarrhalis and allied cocci being prominent.

Dr. Glover Lyon referred to the multiplicity and varying combination of symptoms. Before 1889 respiratory symptoms were most prominent, then the nervous, and from 1892 the gastrointestinal. He thought the increased strain and hurry of modern life accounted for the last phase, and perhaps also for the increase of appendicitis.

Dr. Ford Anderson demurred to the special infectiousness of catarrhal cases and thought temperature the best indication. Whenever there was a rise he found the disease go through the house, and that in nervous and gastrointestinal as well as catarrhal cases. But he thought, too, that sprays and gargles were preventatives. Quinine, 3 grs. t. d. or as much as the patient could stand, gave good results. He distrusts salicylate of soda, and prefers salicin in 20 gr. doses. A coal-tar product to reduce fever if necessary, but the sooner antipyretics were discontinued the better. In bronchopneumonia quinine does not seem to suit, and he resorts to digitalis, ammonium chloride, and nux vomica. The digitalis increases the ventricular contraction, but if the arteries are also contracted nitrites are called for.

Dr. Humphreys thought the cardiac trouble the most important. Patients who seemed well in bed, fell down on assuming the upright posture. The remedy he used in these cases of weak or dilated hearts was digitalis.

Dr. Shadwell thought all cases in which angina pectoris was present were essentially neurotic. By running the finger along the spine, a tender spot will often be felt. The posterior root of a nerve is affected. A blister on the spot will relieve it in twenty-four hours or less, and in two or three days the neuritis or neuralgia is cured.

The president, Dr. F. J. Smith, of the London Hospital, said when it was a question of treating symptoms or the patient, the wishes of the sufferer should be considered. A cup of tea was often the first thing a patient improving asked for, and when he got it he felt on the way to recovery. He used it often in the wards, when the patient had been fed on milk and beef tea. The word neurotic should be reserved for cases in which the will power was most at fault. He was not quite satisfied that in cases called meningitis real inflammation existed, though the pain seemed too persistently severe for neuralgia.

Progress of Medical Science.

Boston Medical and Surgical Journal, June 1, 1905.

A Case of Hemorrhagic Disease of the Newborn.—C. W. Townsend reports the case of a male child who presented at birth a slight ecchymosis on one finger. On the following day he cried considerably and vomited some bloody mucus. An ecchymosis appeared under the chin and on the back of the neck. On the third day several more hemorrhagic spots appeared, and when the child was sixty hours old copious bleeding began from the base of the cord at the navel. At this same time also was passed a large, tarry stool made up of decomposed blood, it vomited fresh blood, bled slightly from the nose and from a minute scratch on the scrotum, and several more ecchymoses appeared on the body. The temperature was 101°. The child now presented a desperate appearance, and the outlook was of the very worst. Nitrate of silver and styptic iron gave but temporary relief. A heaping teaspoonful of gelatin was then dissolved in an ounce and a half of water and given in a nursing bottle, while a 1/1000 solution of adrenalin was applied to the navel. The gelatin was repeated, thumb pressure was made from time to time on the navel, and the patient made a good recovery.

A Description of Pfeiffer's Disease (Glandular Fever), with a Report of Two Cases.—The description is given by A. H. Wentworth who says that the disease is character-

ized by an elevated though brief febrile movement and a rapid enlargement of the cervical glands especially those along the upper third of the posterior border of the sternomastoid muscle. The course is mild and suppuration is rare. The etiology is unknown. It occurs most frequently between the ages of two and eight years. It begins suddenly with a high fever (104°), possibly body pains, usual febrile symptoms, occasionally a reddened throat and a slight nasal discharge. Duration may last from two to ten days. Acute nephritis of the scarlet fever type has been observed as a complication. The location of the glandular swellings is a most important point in differential diagnosis. Prognosis is always favorable. Symptomatic treatment is all that is called for. We should be careful to distinguish the malady from parotitis, tuberculosis, and septic infections.

New York Medical Journal, June 3, 1905.

The Medical Treatment of Gastric Ulcer.—The plan advised by J. Friedenwald consists in rest and a liquid diet gradually thickened, for it must be remembered that an absolute milk regimen may cause anemia. Nitrate of silver in solution may be given (to patients who cannot rest) in solution one-sixth to one-third grain doses for 3 weeks or a drachm of bismuth may be given three times a day. The bismuth may be given suspended in water after lavage of the stomach, the patient being required to lie on his right side half an hour. Another plan is to give olive or almond oil before meals. Oil forms a coating over the stomach and thus assists in relieving pylorospasm. By relieving friction it lessens pain. It checks the excessive secretion of acid and improves the general nutrition. Hemorrhage calls for rest in bed, ice bags, and morphine by hypodermic injection; adrenalin and ergot and gelatin are also at our disposal. For the acidity we may give alkalies with codeine or belladonna. Enemata or oil and Carlsbad water will relieve constipation. Evidences of a healed ulcer are entire absence of pain after eating, no pain on pressure in the epigastric region, and continued absence of blood traces in the stools. Indications for surgical intervention are perforations, perigastric adhesions, hemorrhages, either profuse or small and frequent, persistent nausea and vomiting, and recurring ulcers.

Loss of the Sign Language in a Deaf Mute from Cerebral Tumor and Softening.—The patient of C. W. Burr was a woman of fifty-six years, who had become deaf in early childhood, and had never learned to talk. After her first stroke she recovered consciousness with retention of the power to use the sign language. Three other strokes followed, all within two months of the first, and after the last one she permanently lost the sign language. In about three months from the first attack, she was seized with sudden dyspnea and quickly died. Her general condition was one of right hemiplegia and right homomymous hemanopsia with loss of all power of expresssing or comprehending thought by verbal speech, sign language, writing or pantomime. At the autopsy the left hemisphere was found to be a little larger than the right and the anterior convolutions were flattened. The mesial surface bulged in the region of and just in front of the paracentral lobules. At one point over an area of about one inch in the posterior part of the superior frontal and superior part of the ascending frontal was a dark red soft spot. Palpation over the entire surface gave a feeling of fluctuation beneath. On section the reddish spot spoken of above was seen to belong to a tumor, which extended to the basal ganglia. The tumor was soft and not encapsulated, and was surrounded, except on its cortical aspect, by an area of softening which involved almost the entire white matter of the hemisphere. The basal ganglia on the left side were almost destroyed by softening. The softening was due in part to hemorrhage, in part to thrombosis. Histological examination showed the tumor to be a very vascular glioma.

The Prevention of Insanity in Its Incubation by the General Practitioner.—The plea is put forth by J. T. W. Rowe that the general practitioner should and can prevent much insanity by preventing the toxemia which follows abeyance of function which results from too close application and overwork in unsanitary surroundings. The proper advice should be given to families. The laborer, in his ignorance of the laws of nature, sweats in the darkness. The workers in the factory and the slums; the professional man overconfident in his intellectual powers and well ordered nervous system; the lad at school weighed down by too close application and not enough open air exercise; the shy, retiring boy just yielding to evil inclinations; the worried business man and father bearing a heavy load and seeing no way of lightening it—all these patients are very near the borderland of mental affection, and this is the very time when proper medical advice could avert disaster. Every possible step should be taken to help the sufferer before he is sent to an asylum. Many cases of nervous and mental disease remain for a long time in a curable condition, and it is just at this period that the family doctor's advice and help is of the utmost value. Children, especially, should be carefully watched for the crowded curriculum of the modern school is a potent factor in sowing the seeds of what in after years may develop as an incurable mental disorder.

Medical News, June 3, 1905

The Prophylaxis of Lobar Pneumonia.—From a study of various municipal statistics and other material bearing on the matter, J. M. Anders concludes that the most efficient prophylaxis for pneumonia must have reference to the accomplishment of four principal ends, viz., (1), the overcoming of individual predisposition, (2) the prompt and thorough disinfection of the sputum and secretions of the upper respiratory tract; (3) isolation of the patient especially from those who are debilitated; (4) the disinfection of the sick room together with its contents after either death or recovery; and (5) the observance of certain public measures. The disease is more common since influenza began a few years ago. Predisposing factors are degenerative lesions of the cardiovascular system and kidneys. Under the head of public measures we must include means to prevent dust from accumulating, and its daily removal from home and the city streets are imperatively demanded. Public health authorities should be given full executive power to carry out rules and regulations relative to pneumonia looking to the prevention of its spread, as in the case of other infectious and contagious diseases; they should also carry on a campaign of public education. Measures of prophylaxis must accord with intelligent public opinion before they can be rendered wholly efficient either by municipal or private authority.

A Plea for Medical Treatment of the Inflamed Appendix.—A. L. Benedict believes that the surgery of the appendix has been carried to an unjustifiable point. In reply to the assertion that the cases subjected to medical treatment usually relapse, he replies that the statement is based largely on the consideration of cases that are really not treated at all, but recovering under the use of anodynes. Probably 99 per cent. of fatal cases are due to sepsis within the bowel. In probably 90 per cent. the chief bacteria are the ordinary colon bacilli and other regular inhabitants of the bowel whose virulence has been increased by constipation and opportunity for growth. Now the medical treatment should be based on this conception of the nature of the disease process. The author holds strongly to the belief of the great advantage of free catharsis and if indicated bowel and stomach irrigation. If the patient is so situated that operation is out of the question, it is wise to relieve his suffering by morphine, to splint the bowel with adhesions in the hope that there will be no perforation or migration of bacteria to the peritoneal surface. But in any community in which ordinary conditions prevail it is not necessary to do this. If the case is mild, the prime indication is to keep it so by getting rid of the bowel contents. Calomel should be given in divided doses by a Seidlitz powder. Saline or boric acid injections may be used if there seems to be lodgment in the large intestine, low down. But there seems to be some danger of increasing the trouble by enemata. The patient should fast and drink plenty of water for two or three days. Credé ointment or pipe-clay and glycerin poultices may be applied over the lower abdomen. They do no harm and are really adjuvants. Hot poultices and ice bags seem to me inadvisable. Pain due to spasm, internal irritation and apprehension can usually be relieved by atrophine, cannabis, indica, etc. If severe enough to require morphine, which rarely occurs, in the author's experience, it is severe enough to suggest the need of operation. Septic and gangrenous cases should be at once operated on. The author's plea is for proper discrimination and rational treatment, not neglect under morphine in cases in which operation is unnecessary.

The Effect of Intestinal Antisepsis on the Excretion of Hippuric Acid in the Urine.—From a series of experiments on dogs, J. B. Prager offers the following conclusions: (1) The feeding of gelatin alone increases the excretion of hippuric acid. (2) When putrefactive changes are increased the excretion of hippuric acid is increased and *vice versa*. (3) When the intestinal canal is made antiseptic with calomel there is practically no hippuric acid excreted. (4) Intestinal antisepsis has no effect whatever on the excretion of nitrogen. (5) No matter how much gelatin is fed it is completely burned and some of the body's proteid with it. (6) Therefore gelatin never builds up any tissue, although it may to a certain extent protect the body's proteid from decomposition.

American Medicine, June 3, 1905.

Ischochymia and Its Treatment.—Max Einhorn describes some cases of benign ischochymia with intense peristaltic restlessness of the stomach which were cured by medical treatment. He also reports cases of ischochymia with

a short history of diseases which were benign in character. Two cases are described in which tumors of the pylorus and stomach were seen and palpated during operations and left untouched—the patients, however, recovering entirely and remaining well for many years. The indications for medical and surgical treatment of ischochymia are given as follows: (1) Benign ischochymia requires first medical treatment; if this be unsuccessful, *i. e.* if after a longer period of treatment, the fasting stomach, or a fluid diet, is not empty, but contains food remnants, an operation is advisable. (2) Surgical intervention is also indicated in benign ischochymia which has developed subsequent to a condition of continuous hypersecretion of gastric juice (preceded by hemorrhage or not). (3) Malignant ischochymia or one of dubious nature in which, however, a thickening of the pylorus is found, should also be treated surgically (gastroenterostomy, and, if possible, resection of the pylorus).

Bright's Disease in High Official Circles at the Nation's Capital.—T. L. Macdonald says the strenuous life, excessive mental activity and the corresponding degree of physical quiescence, and years of overindulgence in rich foods, with its associated high blood-pressure, are the essential causes which render Bright's disease frequent in the high official circles at Washington. In conclusion, he emphasizes the following facts: Unemployed food products become toxic irritants and menace the structural integrity of the kidneys. Man is an organism built round an eliminative system; when that is abnormal he cannot be normal. When the balance between ingestion, metabolism, and elimination is absent, danger is present. Apparently nutritional excess is the germ of nephritis. Mental activity and physical quiescence aid in its production. Carking care and the corrosive influence of worry and mental strain render prominent aid in producing it. It is prone to attack the intellectual and the anxious. Alcohol, while affording it encouragement, has been given a too conspicuous place as a causative agent. It is an extremely insidious disease, and is often well advanced when discovered. It is so far-reaching that its first noticeable effects may be visited upon organs and tissues remote from the original disease. The conditions which lead to it are quite amenable to correction if efforts are made sufficiently early. It occurs somewhat frequently at the nation's capital because the congregation of eminent public men means a concentration of worries, wealth, and official feasting.

The Office of the Spleen.—Edward T. Williams, fixed ox and hog spleens with sublimate-salt and stained with hematoxylin-casin. He invariably found nucleated red blood corpuscles, many of them with dividing nuclei. Arteago, by the same method, found them in the spleens of cats and dogs. Proper observations in human spleens are still wanting. The proof is almost complete that the spleen is the true organ for making red corpuscles. No doubt the marrow shares this function, but the marrow is a tissue, not an organ, deriving its property of making blood cells from the primitive mesoderm, of which it is a remnant. In warm-blooded animals it serves as a subsidiary spleen, to supply the extra number of red blood corpuscles required for the maintenance of their bodily heat and increased respiratory activity.

Malarial Infection Presenting Symptoms of Multiple Neuritis.—George E. Price reports a case in a girl, aged 8, who had multiple neuritis of 18 months' duration, following malarial infection. The symptoms were pain, paresthesias, tremor of hands, diminished power in all extremities, particularly marked in the flexors of the ankles, and giving the characteristic "foot drop." There was also a slight intermittent rise of temperature. The malarial parasite, of the estivoautumnal variety, was found in the blood. This corresponds to the findings of Spiller and other observers, in various forms of malaria of the nervous system. Recovery followed the administration of quinine.

Journal of the American Medical Association, June 3, 1905.

Conjuctival Irritation from Animal Emanations.—W. C. Posey gives the history of three cases in which temporary conjunctival irritation was induced by proximity to horses. In all three of the patients there was also more or less nasal irritation, and in one, handling a cat caused similar symptoms, though to a slight extent. One patient was also subject to hay fever. Posey has found no reference to this condition in opthalmologic literature, but finds that nasal irritation from animal emanations has long been noticed by rhinologic specialists. Dr. S. Weir Mitchell, in a personal communication to the author, reported that he had come across many cases of conjunctivitis caused by proximity to cats, and Kyle also informs him that he has seen a number of cases of nasal and conjunctival affection, clinically, almost identical with hay fever, that were excited by animal emanations. Kyle's theory of hay fever is that it is due to some chemical change in the mucous secretions, and he found that in nearly all these cases the secretions showed an excess of the ammonia-salts. While this theory may explain the susceptibility, it gives no light as to the nature of the agents which excite the irritation in the susceptible individuals.

Ice Applications in Lobar Pneumonia.—P. A. Aurness outlines as follows a method of treatment that he claims to have used for a number of years with great success in lobar pneumonia: As soon as a diagnosis is made, the patient is given a full warm bath for cleansing purposes, put to bed and given a laxative dose of calomel and soda. The chest area of the lung tissue involved is carefully outlined, and one or more, as required, specially constructed ice bags are moderately but evenly filled with crushed ice and applied accurately over the parts inflamed. Each bag is wrapped in a thin layer of gauze and is furnished with a drainage pipe, the lower end of which empties into a basin below the bed. The main and important feature is this draining off the water as fast as it is formed, thereby establishing constant and uniform ice application and utilizing the remarkable heat-absorbing quality of melting ice. Examinations are made each morning and evening, and the ice applications adapted to the changing areas of involved lung. There is no danger, he claims, to the vitality of the parts, and the ice applications are kept up as long as the disease appears to be progressing and no threatening signs of collapse appear. In the latter event, ice applications are promptly removed, and stimulation is at once resorted to. The internal treatment throughout the disease, aside from stimulants, includes free use of some mild alkaline mineral water, and five to fifteen-drop doses of creosote every four hours. The bowels are regulated by saline laxatives and enemas, the diet is guided by the digestive capacity, and free ventilation of the sick room is secured. It is claimed that this treatment lowers the pulse while regulating and strengthening the heart, relieves respiratory difficulty and chest pains, and shortens the duration of the disease in the majority of cases. If begun within the first twelve hours, the disease may be aborted.

Large Dose of Quinine in Pneumonia.—F. H. Poole reports that he has recently treated thirteen consecutive cases of pneumonia among Indian school children with large doses of quinine according to the method advocated by Galbraith without mortality. The initial symptoms common to all cases were intense frontal headache, epigastric distress and vomiting, and in eight cases epistaxis also occurred as an initial symptom. Three of the five boys had epistaxis at the onset and all had it repeatedly during the quinine treatment. Of the eight girls, five had it as an initial symptom. Two of these had never menstruated, but the menses appeared during the treatment; in the other three they also appeared, though not due, and in spite of the fact that the patients had always previously been regular in this respect. In none of the girls did epistaxis appear after the initial symptoms. Poole asks: "Was this hemorrhagic tendency a part of the disease and peculiar to this epidemic, or were the epistaxes of the onset due to the infection and the later hemorrhages to the treatment?" The minimum single dose of quinine given was fifteen grains, the largest thirty-six grains. These large doses proved a genuine stimulant to the heart and circulation, and appeared largely to allay the anxiety of the patient and to secure sleep.

The Lancet, May 27, 1905.

Two Cases of Idiopathic General Cataract in Children Closely Related.—T. Hunter reports the cases, one being in a healthy boy of twenty-two months, with complete cataract in the right eye. The other patient was a healthy girl of five years, with cataract in the left eye. The children were natives of India, and first cousins, the father of one and the mother of the other being brother and sister.

Acute Aortitis.—The patient of W. Broadbent was a man of forty-five years, who complained of pain across the left chest after meals, which had come on about three months previously. Examination showed some cardiac hypertrophy, weak impulse, short diastolic murmur, while at the pulmonic and aortic cartilages there were soft second sounds and a short diastolic murmur. There had been no rheumatic fever and no specific history was obtained. Epigastrium was tender, but stomach was not dilated. The patient did poorly under treatment, and died suddenly about a week later. At the post-mortem, the aorta was of a bright red color inside and outside, for its first three inches. The valves were competent by the water test, but were thickened and atheromatous. Areas of old atheroma were scattered over the aortic walls. The intima was bright pink and swollen in patches. No bacteriological investigation was made. The heart muscles seemed firm. The microscope showed a perivascular infiltration of the aortic wall with leucocytes around the vasa vasorum, more marked in the outer coat. As in previously recorded cases of this nature, the lesion was an acute inflammation attacking an aorta already damaged by atheroma. The duration of the

disease from the first symptom which could be called true cardiac pain, was only seventeen days, an unusually short period.

On the Resemblances Existing Between the "Plimmer's Bodies" of Malignant Growths and Certain Normal Constituents of Reproductive Cells of Animals.—The researches forming the basis of this paper were made by J. B. Farmer, J. E. S. Moore, and C. E. Walker. The "Plimmer's bodies" are found in many cancers, most commonly in the younger and growing regions of the neoplasm. They appear as vesicles with a fairly well defined wall containing a clear space in which is suspended a small granule staining darkly. They are most common in tumors of a glandular or glandular epithelial origin. They are regarded as peculiar to cancer cells. Some regard them as parasitic, more or less concerned in the etiology of the disease, while others look on them as a differentiation of the cytoplasm of the cell itself. The authors find analogous structures in the reproductive cells of man and other mammalia. The authors suggest that it is possible that malignant elements are the outcome of a phylogenetic reversion, but the matter is obscured by the disturbing influences which have been operative during the actual ontogeny of the cells and tissues from which these elements have sprung.

On Pneumococcal Sore-Throat with Notes of a Fatal Case.—W. Pasteur reports the history of a boy three and a half years old, with a severe sore throat, but no exudation and no plugging of the tonsillar crypts. Antitoxin was given in large dose. Swab cultures showed many cocci but no bacilli. The course of the disease was that of a severe general infection. The case proved fatal at the end of the third week. The uvula and palatal arches had sloughed before death which was due to bronchopneumonia. Post-mortem cultures from the throat showed the presence of the diplococcus pneumonia in predominating numbers. Gangrene is prone to occur in pneumococcal inflammations of mucous membranes. The local signs of pneumococcus throat inflammations are in no sense distinctive. The culture test alone can decide. The severity of the onset is strikingly like that of pneumonia itself. The disease is generally a short one, from two to five days. The majority of recovered cases have been in adults.

British Medical Journal, May 27, 1905.

Operation for Catarrhal Deafness: Recovery of Hearing After Ten Years of Almost Total Deafness.—F. Faulder White reports this case. The patient was very deaf in the right ear, but with the left ear she had heard nothing at all for about ten years. The writer removed at operation the left membrane with the malleus. There was little pain or other disturbance. Asepsis was carefully preserved and the ear was carefully syringed once or twice daily with a solution of salufer in boiled water. There was some improvement in the hearing in three weeks. About a month after operation the hearing had so improved that the patient could understand what was said by any one six feet away without much raising of the voice. About four months after operation, the writer examined the ear which he found quite healthy. Still four months later, the patient heard more distinctly than she had at any time since the operation. The result was so satisfactory that the writer has thought the case worth reporting.

Two Cases of Unilateral Convulsions and Paralysis in Young Subjects Associated with Exudative Erythema.—T. K. Monro describes these cases. The first patient was a boy of twelve years who, apart from rheumatism, had never been ill before the present attack. Possibly as a result of prolonged bathing, he began to suffer from pain and stiffness in his joints on June 12, 1903. After subsiding, these symptoms were followed by severe pain, vomiting, and diarrhea which continued for two weeks and caused extreme wasting and exhaustion. The patient became almost comatose, and at this time convulsions began. They involved the right angle of the mouth, the right arm, and the right leg simultaneously, and were strictly confined to the right side. The attacks became fewer, and finally in two weeks they ceased. The development of the right hemiplegia and aphasia dated from the convulsive seizures. Sensation was not affected. Striæ atrophicæ were noted on the left leg. On December 26, the temperature began to rise, and on January 4, an eruption of erythema nodosum developed on the legs. A few appeared on the lower parts of the thighs, and one on the right forearm. This attack of erythema was not associated with arthritis or with subjective symptoms. As to the theories concerning the pathology of such cases of hemiplegia, on the one hand it is supposed that the cerebral lesion results from vascular obstruction. Gowers favors the idea of thrombosis in the artery or in a vein on the surface. Moreover, Strümpell has suggested that the disease is acute polioencephalitis. The linear atrophy seen in this case is a very interesting feature. The second patient was a girl eighteen years old. Convulsions were followed by right hemiplegia. Sensation was preserved. Erythema multiforme appeared. Optic neuritis was noted. The writer believes that it is likely that in cases of hemiplegia of this nature the lesion is not a constant one. It is reasonable to suppose that in many of them the primary condition is thrombosis, which may or may not from the outset or at a later period be infective in its nature, and thus liable to give rise to inflammation in its neighborhood. He states that the association of exudative erythema with this disease does not find mention in the textbooks.

Some Experiments in the Treatment of Trypanosomiasis.—H. Wolferstan Thomas has used in his experiments an aniline compound, containing 37.69 per cent. arsenic, and claimed to be forty times less toxic than Fowler's solution. It is very suitable for subcutaneous or intravenous administration. It causes no pain, and no necrosis, and much higher doses of arsenic can be given without producing toxic results. The results of the administration to various animals infected with trypanosomiasis, of this drug, were very successful, and the writer declares his belief that treatment is indicated in cases of trypanosomiasis in man with this drug in high doses administered intravenously, and for a long period, pushing it to the maximal amount that the case can stand without headache and nausea, at the same time building up the patient in every possible way, that will tend to lessen the anemia. The writer adds that he does not believe that sodium arseniate alone will be found of great practical value nor does he think that the present is a perfect preparation, but it is an advance on arsenious acid. If further efforts be made to produce a substance like trypan red, but less irritating in action, the combination ought to be of service in the treatment of trypanosomiasis in man.

Berliner klinische Wochenschrift, May 15, 1905.

The Combination of Excision and of X-Ray Treatment for Exophthalmic Goitre.—Carl Beck says that although precise knowledge in regard to exophthalmic goitre is still lacking, the consensus of opinion among observers is that the condition is one of systemic intoxication dependent on defective chemism of the thyroid gland. The results obtained by Kocher, who relieves the exalted vascularity of the region by ligation of the enlarged vessels, together with extirpation of one-half of the gland, are excellent but still leave much to be desired. The expected benefits do not follow in a considerable proportion of the cases, and in about three-quarters of all cases severe sequelæ are observed, such as a tendency to psychoses, increasing nervous excitability, facial congestion, palpation, tremor, vomiting, fever, cold sweats, cyanosis, etc. The author's observations on the effect of the *x*-rays on new growths of the circulatory system led him to note their specific effect on the vessel walls and induced him to try their application for the relief of the extreme vascularization of this disease. In order to secure the greatest effect unilateral extirpation is an advisable preliminary, and the author mentions two cases in which radiotherapy produced very beneficial result over a year after the partial operation had been done with only partial relief of the symptoms. Another case is described at greater length, and in this the rays were employed about a week after the operation. The result was extremely gratifying, the tachycardia and dyspnea promptly subsiding so that a week later the pulse rate was only 80, the exophthalmos had almost completely subsided, and the general condition was excellent. Some months later a perfect cure had been effected. Beck accordingly advises, for mild cases that have resisted internal therapy, general treatment combined with the *x*-rays, while in those of great severity unilateral extirpation should also be done.

Changes in the Nails After Acute Diseases.—Eger calls attention to the fact that changes in the finger nails are much commoner than it would appear from the scanty comments on this subject to be found in the literature. The few writers who have interested themselves in the subject have usually tried to establish a specific relationship between ungual alterations and certain diseases, such as typhoid or scarlatina, but the author considers that this is far-fetched. He says that the various transverse ridges or furrows appearing as the nail substance is pushed forward into view from the matrix simply represent a stage of defective nutrition during the period of illness. The groove indicates a certain degree of death of the nail, and the succeeding ridge is probably due to a reactive cellular proliferation intended to dispose of the dead portion. He describes three cases of widely different nature, viz., multiple neuritis, typhoid fever, and toxic gastroenteritis, in all three of which the nail markings subsequently appearing were similar in appearance.

Münchener medizinische Wochenschrift, May 16, 1905.

The Treatment of Acne by Means of a New Operative Procedure.—Kromayer has already advocated this method for the purpose of removing superfluous hair, and he now lauds it highly in the treatment of acne. A special form

of rotary cutter is employed which consists of a minute steel tube with a sharp edge at one end. This can be made to revolve rapidly after the manner of a dental drill. The cutters are used in different sizes; those ranging from 0.7 to 1. mm. in diameter, cause wounds of the skin which heal without any scar formation. The operative technic is very simple, the rapidly rotating cutter is pressed vertically into the skin at the site of the pustule until the subcutaneous connective tissue is reached. On withdrawing the cutter a tiny plug of tissue is left behind which may easily be drawn out with forceps. In this way the acne lesion is treated surgically as an abscess should be, by drainage, a plan that has heretofore not been feasible owing to the scarring that would be produced by any ordinary method of incision. The author says that the treatment may be used as a prophylactic measure to prevent the formation of acne lesions in indurated comedos, as an abortic measure in beginning pustules and as a curative procedure in those already fully formed. The pain caused is not more severe than that of a pinprick, and most patients do not require any local anesthesia. The punctures heal promptly, so that ladies who have been operated on in the morning have appeared in public in the evening without presenting any traces of the treatment.

A New Field for Radiotherapy in the Treatment of Goitre.—Görl has tried radiotherapy in goitre, with what he considers very encouraging results. Seven cases were treated, and in all there was marked diminution in the size of the growth as well as improvement in the other symptoms. The author believes that it is primarily the parenchyma cells that are affected by the rays, and not the blood vessels, as the diminution in size of the gland begins so promptly and takes place so uniformly. Medium soft, or soft tubes were employed, and at a comparatively short distance from the skin. Care is necessary to prevent burns; in one case the author found that the patient's skin was unusually sensitive to the rays, and he suggests that this condition may be one of the symptoms of the disease.

Hebotomy.—Hammer describes two cases in which this procedure yielded excellent results both for mothers and children. The one patient had a generally contracted rachitic pelvis with a true conjugate of 8 cm., and a very large child. The other pelvis was of the flat rachitic type with a true conjugate of 7 cm. In each instance the operation was easily carried out, though there was some difficulty in performing the forceps extraction. In the one case as there was no cause to suspect infection, a cesarean section might have been done to secure a living child, but in the second case perforation was the only alternative, as the earlier part of the labor had been conducted under unfavorable conditions and the mother already had a rise of temperature. The author considers as an advantage of hebotomy over symphyseotomy the fact that after the former the severed bone ends separate but slowly, so that there is less danger of injury to the soft parts. The incisions were drained from below in both instances, the upper wound being entirely closed by suture.

Deutsche medizinische Wochenschrift, May 18, 1905.

Karlsbad or Kissingen?—Boas takes these two baths as types of the two great classes of such resorts, Karlsbad representing the hot springs and Kissingen the sodium chloride waters. He first points out the general difficulties in selecting cases likely to profit by treatment of this form, and accentuates the fact that while many almost miraculous cures are effected by drinking cures, or by baths, on the other hand injudicious recommendation of patients to such places often results in bitter disappointment. A rule too often neglected is that no patient should be sent to a watering place if there is any uncertainty as to the nature of his illness. Hyperchlorhydria and ulcer of the stomach are most apt to be beneficially affected by sojourn at one of the sulphate springs, like Karlsbad, but not every case is suitable for this form of treatment. Karlsbad is especially useful in completing the cure of gastric ulcer. The sodium chloride waters are especially adapted for the gastric conditions characterized by deficiency in hydrochloric acid, but care is essential not to overlook carcinoma or other contraindications. Disturbances of motility and neuroses are not proper conditions for these baths. Of the enteric diseases, chronic catarrhal conditions do best at Karlsbad, while constipation requires the cold, sulphate waters of the Kissingen type. Patients with hemorrhoids also are better sent to the latter class of resorts. In perityphlitis the cold sodium chloride and the sulphate springs are preferable, but nervous affections of the intestines, like those of the stomach, derive little help from water cures.

The Treatment of Epidemic Cerebrospinal Meningitis.—Franca is greatly pleased with his results in the treatment of this disease by means of intraspinal injections of lysol. His method is to withdraw 25 to 50 c.c. of the cerebrospinal fluid and then to inject one per cent. lysol solution into the canal. The amount is graded according to the age of the patients, adults receiving from 12 to 18 c.c. and children 3 to 9 c.c. In severe cases the injections are continued every day until the cerebrospinal fluid becomes sterile, a result that is usually obtained in a few days. The injection gives rise to slight pain which soon subsides, and the only sequela of the treatment is the development eight to ten days after the first injection of a yellow discoloration of the palms of the hands and soles of the feet, which is followed by active desquamation. In cases in which the fluid is very purulent the canal is flushed with salt solution before injecting the lysol. The treatment is said to shorten the course of the disease, to prevent the occurrence of relapses and to cause rapid disappearance of the diplococci. There is less emaciation and fewer trophic disturbances, while mental disorders, paralysis, and disorders of the sensory system are rare. Of forty-seven cases treated by lumbar puncture thirty died, of nine in which cyanate of mercury was injected six died, and of fifty-eight in which lysol was used, only seventeen died. In several cases of tuberculous meningitis the method was found to be ineffectual.

Artificial Respiration.—Herter discusses the various methods in vogue for carrying on artificial respiration, including those of Marshall Hall, Sylvester, Howard, and Brosch. He points out that certain defects, either in effectiveness, in the possibility of injury to the patient, or in the great fatigue of the operator produced, are inherent in all of these. His own procedure is a combination of the best features of all four and comprises the following steps. The mouth and pharynx are quickly cleared with a handkerchief over the forefinger, and the patient with his chest exposed and the clothing about the waist loosened, is laid with the hypogastrium over a firm pad made of any available material. By several rapid pushes on the back an attempt is made to force any existing fluid out of the stomach or air passages, and the patient is quickly turned on the back so that the pad causes the costal arch to project. The tongue is drawn forward and entrusted to an assistant to hold by means of a handkerchief, and then the costal border is rhythmically compressed according to Howard's method while the arms are manipulated in the way described by Sylvester, the downward pressure of the elbows being made as near the middle line of the body as feasible. If possible four persons should be engaged in the work, one to hold the tongue and give the tempo by counting out loud his own respirations, one to compress the ribs from below, and one to each arm, but if needs be, the number may be reduced to one, who must then confine himself to placing the patient's arms above his head and kneeling astride his body while he holds the tongue with one hand and with the other compresses the costal arch.

French and Italian Journals.

Tuberculous Meningitis Ending in Recovery.—Claisse and Abrami report this case. The patient was a man thirty-four years old, with a good personal and family history. The symptoms were vague at first, and seemed more like those of ordinary grippe. But rapidly and suddenly there appeared very clear and distinct symptoms of meningitis: delirium, violent hallucinations, obstinate constipation, headache, pupillary disturbances (inequality, paradoxical reflex, and so on). Lumbar puncture, made on the second day, showed an bundant and pure lymphocytosis. In spite of the absence of the Koch bacillus in the preparations, these men believed that they were authorized in making the diagnosis of tuberculous meningitis of the delirious type. The case was considered hopeless, and a new puncture was not made. After eight days, however, improvement which was progressive and distinct took place. It was complete at the end of a week and now for two months there has been no relapse. On account of this unexpected course of events, these investigators believed that an error in diagnosis had been made. In order to verify this, they practised a second lumbar puncture at the beginning of the period of improvement, and a third, fifteen days after the complete disappearance of every morbid phenomenon. But while the first puncture, that of the second day, had revealed a very clear lymphocytosis, the second and the third did not show any. There was proof then of both a clinical and an anatomical recovery. On the other hand, inoculation of a guinea pig, with the liquid from the first puncture, resulted in a tuberculous sore at the point of inoculation. The authors believe that the prognosis of tuberculous meningitis ought to be revised.—*Le Bulletin Médical,* May 17, 1905.

Appendicitis and Tuberculosis of the Appendix.—Maurice Letulle declares that the occasion is very rare for the surgeon to operate on an appendix that is both inflamed and infected with the tubercle bacillus. Two cases have recently come under his observation, however. In the first instance, a surgeon operated on the patient

and removed a tuberculous appendix. The appendix also showed that the patient had been suffering from chronic follicular appendicitis, the organ being dotted with tuberculous foci. In the second case, the patient had acute attacks of non-tuberculous appendicitis with a cascous-bacillary background. The patient was also a victim of pulmonary tuberculosis. The appendix showed two distinct kinds of lesions. There was advanced tuberculosis of the appendicular mucosa, with caseous pus and giant cells. In the places where the mucosa was not destroyed by tuberculosis, it was easy to recognize the non-tuberculous lesions of acute follicular appendicitis. Although acute appendicitis is not rare in the course of chronic tuberculosis of the appendix, it rarely comes under the hand of the surgeon, sometimes because of its habitual mildness, and at other times because of the fact that the patient is suffering elsewhere from tuberculosis. Tuberculosis of the appendix, commonly ulcerative, does not appear to favor the development of acute secondary infections which are apt to give rise to attacks of acute non-tuberculous appendicitis.—*Revue Française de Médecine et de Chirurgie,* May 15, 1905.

Cutaneous Syndrome of Gastrointestinal Origin.—M. L. Jacquet describes the case of a young woman who consulted him in September, 1901, for a combination of complex cutaneous disturbances—alopecia, seborrhea, hyperidrosis, pityriasis, hyperesthesia, and pruritus. The patient had suffered from gastric disturbances for a long time, for she had eaten in a gluttonous manner without masticating her food. Believing that this cutaneous syndrome was due to the traumatic excitation of the gastrointestinal mucosa, an excitation reflected and propagated by means of the great sympathetic and the vagus, Jacquet tried the following experiment: The only treatment instituted consisted in the regulation of the patient's food (in the beginning, an exclusive milk diet; later, four small ordinary repasts taken very slowly). The cutaneous symptoms improved rapidly and the patient made a complete recovery.—*La Presse Médicale,* May 13, 1905.

Cancer of the Cervix Treated Successfully by Radiotherapy.—Haret describes this case. The patient was sixty-five years old, and had been refused an operation on account of her age and the invasion of the vaginal wall. Radiotherapy was tried, with one sitting a week. The lesion was treated with the direct rays, while the vaginal was protected by a glass tube impermeable to the *x*-rays. After the second sitting the pain decreased, and after the sixth, not a trace of the primitive lesion could be either seen or felt. The ulcerated parts were cicatrized. Cases of this kind are rare, according to Haret, for surgeons are not apt to subject cervical cancer in the first stages to treatment by the *x*-rays. Early treatment is an important factor in radiotherapy.—*La Presse Médicale,* May 13, 1905.

Results of Serum Therapy in Syphilis.—A. Risso and A. Cipollina publish the results of experiments in the treatment of syphilitics in the secondary and tertiary stages, who had never had any specific treatment, by the use of a serum obtained from injections of animals with the blood serum of syphilitic cases in the secondary, or contagious stage. The injections were made three or four times during five or six days, and after an interval, the animals were killed and the serum prepared from the blood and solid organs. There were 16 cases treated, 14 secondary, 2 tertiary. Of these nine were definitely cured without any other treatment. In all the eruptions, macular or papular, disappeared with greater rapidity than under mercurial treatment. In two cases the result was doubtful. One of the cases had gumma of the nose, cured after 12 injections. Two cases, still in the early stages of treatment, are improving at the time of writing. The disadvantages are not greater than in the use of the other sera: slight rashes, temperature reaction and local pain. The action of the serum is probably specific, or the serum may act as a stimulator of the tissue changes, as mercurials do. The cases should be followed up for a year or more, in order to give a definite opinion of the results.—*Annali dell' Istituto Maragliano per lo Studio e la Cura della Tuberculosis,* October, 1904.

Serum Therapy of Pneumonia.—E. De Renzi gives us his conclusions as to the effect of the antipneumococci serum of Pane, after its use in several cases. It has of late been demonstrated that this serum produces the formation of antibodies in the blood of the patient, which affect the infecting microbes. These antibodies are specific against the bacteria producing the disease. The author's conclusions are as follows: (1) The general condition of the patient improves after the injection. (2) The temperature falls rapidly and the pulse and respiration decrease in number. (3) The serum has little effect on the local condition in the lungs. (4) Resolution occurs by lysis instead of by crisis. (5) Vascular pressure is lowered for a few days.—*La Riforma Medica,* May 13, 1904.

Vaccination Against Tuberculosis.—Maragliano recommends to all physicians an effort to vaccinate patients of tubercular families, in order to test the value of such inoculation, which can only be determined after years of observation. The inoculation should be practiced in country districts, where the practitioners know the people intimately, and know which families have a tendency to tuberculosis. The injections are made with a hollow lancet, which makes a circumscribed lesion. The result is an infiltration, which suppurates in the center, the suppuration reaches its height in three days and is ended on the eighth day. The thermic reaction is not constant, and lasts three or four days. The axillary glands are swollen, and there remains a slight local infiltration. The procedure is entirely harmless, and agglutinines are produced in all cases. The author has injected 24 subjects in the past year, mostly babies.—*Annali dell' Istituto Maragliano per lo Studio e la Cura della Tuberculosis,* September, 1904.

Earth Temperature and Diarrheal Diseases in Dublin During 1904.—Sir John W. Moore first refers to Ballard's work in relation to this subject. During the last year a Climatological Station has been established within the precincts of the University of Dublin. Diagrams have been formulated presenting the results of the observations made in 1904. In the epidemic season, weekly measurements of an inch or upwards of rain on two occasions seem to have been followed by a decline in the number of deaths from diarrheal diseases. Diarrheal mortality was trifling till the week ended August 6, that is, the third week after the subsoil temperature at four feet had passed above 56° F. The mortality, as the writer states, rapidly increased till the week ended August 27, in which thirty-five deaths from diarrheal diseases were registered. This maximum of mortality followed the maximum of warmth of the soil at four feet (58.5°) by an interval of just a fortnight. Diarrhea is rapid in its course, killing very young children usually within a week. In the months of July, August, and September, the deaths from diarrheal diseases are a noted feature of the mortality statistics. From July 3 to October 1, 1904, there were two hundred and forty-three deaths recorded in the Dublin Registration Area. The mean of the readings of the 4-foot earth thermometer during these months was 57°. The writer declares that this was a remarkable coincidence, to say the least, as this figure is only one degree above the "critical" temperature of 56° F. It has been observed that breast-fed infants are notably exempt from fatal diarrhea. The type of bacillus most commonly found in diarrheal diseases along the Atlantic seaboard of the United States is that known as the Flexner-Harris. An interesting point in regard to food is, as Ballard's observations go to show, that the exposure of food to telluric emanations tends to render it liable to cause diarrhea, especially when it is stored in places dark and ill-ventilated.—*The Dublin Journal of Medical Science.*

The Use of Iodide of Silver in Urethritis.—E. H. Siter and A. A. Uhle find that solutions of this remedy cause absolutely no burning and no irritation. Excellent results have been secured in cystitis of prostatic origin and after prostatectomy. The remedy is suspended in a five per cent. solution of quince seed mucilage. The advantages over the various proprietary silver salts is that it is not proprietary, and that the exact strength can be controlled as the strength of nitrate of silver can be controlled. Their experience with the proprietary salts is that they vary considerably in strength, in addition to which is the fact that their exact composition is unknown. The advantages over the nitrate are that the iodide does not stain and is less irritating, which permits of stronger solutions being used and the resulting benefits obtained thereby. They do not put forth the claim that it will work wonders, or that urethritis is reduced by it to the class of trivial complaints; but it can be said for it that it does reduce the acute stage to a minimum, and that it relieves the acute symptoms almost immediately. It is possible to commence the local treatment at once, and with no bad results. Histories are given of eight cases.—*University of Pennsylvania Medical Bulletin.*

Book Reviews.

Surgical Diagnosis. A Manual for Practitioners of Medicine and Surgery. By Otto G. T. Kiliani, M.D. New York: William Wood & Co., 1905.

This book constitutes the most recent as well as the most extensive work of its kind in the English language; indeed, we may say it is the only work of its kind, previous works dealing solely with the diagnosis of surgical affections being now out of print. Its object as stated by the author is two-fold: to describe as exactly as possible the symptoms peculiar to a disease on which the diagnosis can be based, and wherever feasible to teach how to observe these symptoms. The book is addressed primarily to the general practitioner, who is often called upon to decide whether or not a disease needs surgical interference, but may lack the technical diagnostic experience acquired by the surgeon in his routine work. These claims are well met. The author, a pupil of Volkmann and Schede, has had an extensive operative and clinical experience and aims to present the consensus of opinion of the recognized authorities in addition to his own views. These, as regards operative interference in various conditions, are in no way extremely radical, which is an excellent feature. Thus, for example, in the case of a movable kidney, he claims that operation is only indicated when there is sufficient mobility to produce a kink in the ureter or if the condition seriously interferes with the individual's occupation. In acute appendicitis he wisely adheres to the idea that this is a strictly surgical disease for which there is no internal treatment. In other conditions his views are likewise marked by common sense and will undoubtedly appeal to the reader.

In the introductory chapter, the various methods of examination and their application are fully discussed. The special part of the book is arranged in anatomical sequence, beginning with the head, all the organs being considered in detail. Excellent schemes for rapid differential diagnosis are introduced in various parts of the work, and at the end are presented tables of identical symptoms found in various diseases, and of the diagnosis of the various forms of trembling and coma. The book is well illustrated with a large number of plates, many of them being skiagraphs and exceedingly well done. The general construction of the book, its printing, and binding are all excellent.

Diseases of the Heart and Aorta. By Thomas E. Satterthwaite, M.D., Professor of Medicine in the New York Post-Graduate Medical School; Consulting Physician to the Post-Graduate, Orthopedic, and Babies' Hospitals; President of the Medical Association of the Greater City of New York. New York: E. R. Pelton, 1905.

This volume of about three hundred pages represents the author's views and deductions founded upon long experience in this special field. Throughout the work he cites examples, tables and records taken from his histories, and thereby gives a personal stamp to his text.

His endeavor to be clear and yet concise has been successful, and to gain space for the more common cardiac affections he has entirely sacrificed the uncommon, thus affording a book which can be helpful to the ordinary practitioner.

In the diagnosis of the valvular lesions, the newer and more accurate points are given, and the usual errors of the text-books are eliminated.

The most original portion of the work is noted under the chapters on treatment. Here the author gives in detail not only the medication suitable for different conditions, but also the treatments by aërated baths and resistant movements. He has modified these in accordance with American demands, and has given an exceptionally large number of illustrations of the muscle movements which otherwise might not be accurately followed.

The portions allotted to the aorta are not as satisfactory as are those on diseases of the heart. The author, however, disclaims any intention of writing an encyclopedia on the subject, but rather a guide to the general practitioner of a concise and practical nature. In this he has succeeded, and the work can be recommended as accurate and helpful.

The Thyroid and Parathyroid Glands. By Hubert Richardson, M.D., Late Pathologist to Mount Hope Retreat; Pathologist to Maryland Asylum and Training School for Feeble-Minded Children; Demonstrator of Physiologic Chemistry, University of Maryland. With seventy-seven half-tone illustrations made from special drawings by F. P. Wightman. Philadelphia: P. Blakiston's Son & Co., 1905.

It is a distinct pleasure to read a book like the one before us, so replete is it with the latest researches and clinical proofs. The subject has been treated in a masterful and interesting manner, and is bound to interest all medical men from the physiological chemist to the general practitioner. The author sketches the history of our developing knowledge of the typhoid gland, and follows with the embryology, histology, and anatomy of that organ, together with the parathyroids. Then two interesting chapters on the physiology and chemistry of these glands immediately precede the bulkier part of the volume which is of special use to the clinicians. Goitre, the surgery of the thyroid, its behavior in infectious diseases, its diseases and their treatment, are all excellently handled chapters, and contain much that is new and practical. Many illustrations of cretins, exophthalmic goitre, simple goitre, etc., add interest to a subject fascinating in itself, but doubly so in view of the fact that it is developing along lines which relieve human suffering. This work should be read, digested, and its lessons followed out by all who are interested in advancing the art of medicine.

Leçons de Clinique Obstétricale, par le Dr. Queirel, Professeur de clinique obstétricale à l'école de médecine et de pharmacie de Marseille, Membre correspondant de l'Académie de Médecine. Deuxième série. Avec une Préface du Professeur Pinard. Paris: G. Steinheil, 1905.

This is an interesting collection of clinical lectures on various subjects more or less connected with obstetrics. About one-fourth of the volume is on syphilis (viewed from various standpoints); other subjects treated are: ventrofixation, nephropexy, hysterectomy, version, cesarean section, symphyseotomy, and various complications of pregnancy and labor.

A Handbook of Nursing. Revised Edition. For Hospital and General Use. Published under the direction of the Connecticut Training School for Nurses connected with the General Hospital Society, New Haven, Conn., Philadelphia, and London: J. B. Lippincott Company, 1905.

Rarely have we seen a book so unpretentious and yet so thoroughly good and reliable. Both hospital and private nursing are considered; and the nurse's duties from the standpoint of herself, the patient, and the physician, are clearly and pleasantly enunciated. All the directions are practical, intelligible, and comprehensive. Not only is the instruction given both accurate and up to date, but we have not discovered the omission of any important topic concerning which a nurse would be likely to seek information. We have read the book through with much interest, and can cordially recommended it to physicians and nurses.

A Reference Hand-Book for Nurses. By Amanda K. Beck, Graduate of the Illinois Training School for Nurses. Philadelphia and London: W. B. Saunders & Company, 1905.

This little book contains the notes made by the author as a probationer and as a trained nurse; there are also a few articles by physicians and superintending nurses. In spite of the author's statement that while rewriting her notes for the fourth time, "the inspiration followed that my notes in a book form would be of general use to most nurses and of some use to many physicians," we think that the book has too many errors, both of omission and commission, to be considered a satisfactory reference handbook for nurses.

Wharton and Stillé's Medical Jurisprudence. Vol. I. Mental Unsoundness. Legal Questions by Frank H. Bowlby of the Publishers' Editorial Staff. Insanity; Forms and Medicolegal Relations, by James Hendrie Lloyd, A.M., M.D., Neurologist to the Philadelphia Hospital; Physician to the Methodist Episcopal Hospital; Consulting Neurologist to the State Hospital for the Chronic Insane at Warnersville, Pa. Fifth Edition. Rochester, N. Y.: The Lawyers' Co-operative Publishing Company, 1905.

The first volume of this well-known system of legal medicine, devoted to a consideration of the jurisprudence of insanity, has undergone a very thorough rejuvenation. The general plan of the fourth edition has been followed, but twelve new chapters have been added to the purely forensic department of the work, and while the substance of the former editions has been preserved the material has been brought to date by the incorporation of the numerous decisions lately rendered. The second part of the volume, comprising thirty-nine chapters, is entirely new and comes from the pen of Dr. Lloyd. This is an extensive exposition of the medicolegal bearings of mental disease from the standpoint of the alienist, and the complex problems involved are covered in admirably clear and logical fashion. Although perforce more or less philosophical in tenor, the subject matter is skilfully handled and may be read with pleasure and profit even by those less interested in the practical application of the legal points at issue. Seen from this point of view, the study of psychiatry takes on fresh aspects which cannot be neglected by the clinician, and this exhaustive treatise may be warmly commended to all interested in the branches discussed.

Society Reports.

THE PRACTIONERS' SOCIETY OF NEW YORK.

195th Regular Meeting, April 7, 1905.

The President, Dr. Charles Stedman Bull, in the Chair.

On a Case of Hemophilia, with Special Reference to the Joint Symptoms.—Dr. Francis P. Kinnicutt read this paper. (See page 881.)

Dr. Virgil P. Gibney said the joint lesions of hemophilia might readily be mistaken for a tuberculous or other form of arthritis. He could not recall many such cases, but had never before had his attention so forcibly called to the matter. In one case that was now under his observation in the hospital, the patient was under treatment for what was supposed to be a tuberculous arthritis of the knee. Instead of following the usual methods of treatment, however, the joint was simply being protected with a perineal crutch, this conservatism being deemed wise because the patient was known to be a bleeder. He recently had a loose tooth extracted, and the hemorrhage from the gum persisted for several days. The blood count also showed a marked improvement from week to week.

Dr. Kinnicutt, in reply to a question, said that so far as he could recall, the urine showed nothing abnormal during the absorption of the large masses of blood. The absorption, as a rule, took place very rapidly.

Dr. Robert Abbe said he had never seen an abdominal hemorrhage in hemophilia. Such an occurrence, he thought, must certainly be very rare. The possible joint complications of the disease should always be kept in mind by the surgeon, because cutting into such a joint would menace the life of the patient. The speaker thought that chloride of calcium was the most efficient therapeutic agent in the constitutional treatment of hemophilia, as it was also valuable in the treatment of patients before operation for gallstones to prevent hemorrhage.

Dr. Edward G. Janeway mentioned the case of a boy, a hemophiliac, who had a hemorrhage into the spinal canal. There was gradually increasing paralysis, extending upwards, and death occurred in the course of a fortnight. An autopsy showed that the hemorrhage was subarachnoid, but in the lower section of the canal the blood had burst through the arachnoid and partly invaded the dura. The speaker said this was the only case of the kind he had ever heard of.

Dr. Beverley Robinson said he had seen a number of cases of hemophilia, but none exactly similar to the one reported by Dr. Kinnicutt. In a case under treatment in St. Luke's Hospital some years ago the patient was a woman who bled from the uterus, gums, nose, and various other organs, and the hemorrhage was very difficult to check. Cases of recurrent and severe nosebleed were comparatively common, and often difficult to control permanently.

A Tumor of the Eyelid Treated with Radium.—Dr. Robert Abbe presented a man, 45 years old, who had been referred to him by Dr. Peter A. Callan on account of a suspicious tumor involving the right lower eyelid on its free border and both surfaces. It was originally about the size of a hazel-nut, *i. e.* one and one-half centimeters long by one centimeter thick and one centimeter deep, and had resisted six weeks of *x*-ray treatment. It had been there one year, and was gradually growing larger. It had all the clinical appearance of epithelioma. It was itchy, gave rise to a disagreeable discharge, and bled freely on contact. Three applications of the radium had been made one month ago, and one recently, and under its influence the tumor had almost disappeared, being now, after six weeks, not more than a fiftieth of its former size. Dr. Abbe said he hardly thought any further applications would be necessary, but he would report the final result later. The radium used was in three sealed tubes, one of ten centigrammes of Curie radium chloride (300,000), one of 5 cg., same strength, and one of ten mg. German radium bromide (1,000,000).

A Tumor of the Jaw Treated with Radium.—Dr. Abbe also reported the case of a woman, 86 years old, who had been referred to him by Dr. Janeway about two months ago. She had a fracture of the lower jaw on the left side, while the other side was occupied by a growth involving the bone and extending into the mouth. The growth was fungous in character, bled readily, resembled sarcoma, and had involved the bone to such an extent that shortly afterwards a spontaneous fracture of that side of the jaw occurred. A small incision was made into the growth; into this the tube of 10 cg. strongest radium was inserted and tied and allowed to remain for over six hours. As a result of this single exposure to the action of the radium, the growth had shrunk to a comparatively small size; it had become fibrous in character, and had ceased to bleed. The growth had not yet been examined microscopically, but it had all the appearances of a giant-celled sarcoma.

A Case of Apparent Addison's Disease, with Cure.—Reported by Dr. W. Gilman Thompson. The patient was a young man of 26, who came under the speaker's observation at Bellevue Hospital with all the classical symptoms of Addison's disease. He was very dull and languid, and while his face and hands showed very little pigmentation, the rest of the body was of a walnut or brown color, with leucoplakia on the chest. The buccal muous membrane and hard palate also showed patches of pigmentation. The internal organs, so far as could be made out, were normal. He was suffering from an ordinary secondary anemia, the red blood cells being reduced to less than 2,000,000 and the hemoglobin to 20 per cent. He had constant vomiting, a very feeble pulse, and great prostration.

In addition to proper rest and died, the patient was given adrenalin chloride by mouth, and gradually his nutrition improved, he gained in strength and became lighter in color. He remained in the hospital eight months, when he was discharged entirely cured, with a white skin and normal blood count. During his stay in the hospital the tuberculin test was applied three times, and each time there was a decided reaction to the injection, but there was no evidence of any tuberculous process unless the adrenal bodies were involved.

The question naturally arose, Dr. Thompson said, whether this was a true case of Addison's disease, or one of vagabond's disease simulating Addison's. The man had been a tramp for five years prior to his admission to the hospital, and admitted not having had a bath for two years. On the other hand, vagabond's disease would hardly have presented such a group of symptoms as were observed in this case, including the mouth pigmentation and tuberculin reaction. Under treatment, the red blood cells increased from 1,900,000 to 6,800,000, and the hemaglobin from 20 to 90 per cent.

In a somewhat similar but less extreme case observed at the Presbyterian Hospital, some years ago, the patient improved markedly under the administration of adrenalin, and most of the pigmentation disappeared. That patient also reacted to tuberculin, although no evidence of tuberculosis could be demonstrated in the lungs or elsewhere in the body.

Dr. Charles L. Dana, who had seen the case reported by Dr. Thompson, said the patient had been repeatedly examined by members of the staff, and all had agreed that it was an example of Addison's disease. The speaker said he recently saw a woman whose skin over the entire body was almost as black as a negro's as the result of the repeated application of plasters to the skin. After such an application, the pigmentation of the skin would immediately develop and become permanent. In addition to this, the patient had many symptoms of a lack of vascular tonicity, and the case was regarded as one of renal inadequacy. She was given adrenalin, and under this the pigmentation soon disappeared, and the patient's general condition improved very much. Possibly, Dr. Dana said, there were cases of suprarenal inadequacy, or borderland cases, that had not yet developed into Addison's disease. This idea had first

been suggested to him by Dr. Joseph Fraenkel, who was quite firmly convinced that in suprarenal inadequacy we had to deal with a pathological condition that could be recognized and effectually treated.

Dr. JANEWAY mentioned a case of supposed Addison's disease that was kept under observation for a long time at Ward's Island. The pigmentation gradually cleared up, and the physicians came to the conclusion that it was vagabond's disease. The speaker also referred to the possibility of arsenic being the cause of a brownish discoloration of the skin in certain cases.

Dr. Thompson, in closing, said that patients with Addison's disease did not invariably show discoloration of the skin of the face. In one case coming under his observation, in which the diagnosis was confirmed at autopsy by the presence of tuberculous adrenals, the face remained white, although the body was almost as dark as that of a negro. In another case treated at the Presbyterian Hospital, the face had become so dark that the patient had been refused service at different restaurants, under the supposition that he was a negro.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON PEDIATRICS.

Stated Meeting, Held April 13, 1905.

DR. L. E. LA FÉTRA IN THE CHAIR.

A Case of Congenital Defect of Some of the Muscles of the Shoulder Girdle.—Dr. CHARLES HERRMAN presented photographs of a patient, a child two years old, of healthy appearance, whose mother had given birth to two other children, both normal. The patient was breast fed and cut his first teeth when eleven months old. There were no signs of rickets and the patient was of fair intelligence and without previous illness. Almost immediately after birth it was noticed that the child could not raise the arm above a right angle to the chest. The congenital muscular defect was noted in the trapezius, the serratus magnus, the rhomboid and possibly the clavicular portion of the pectoralis major. There were no fibrillary twitchings or other congenital defects. These cases seemed to resemble the progressive muscular dystrophies of Erb, the juvenile form. Dr. Herrman advanced the hypothesis that they began in intrauterine life and ceased after birth.

A Case of Hemophilia in a Girl of Eleven Years.—Dr. MATTHIAS NICOLL, JR., presented this child whom he had observed since last December. There were no other cases of hemophilia in the family. When she was six years old it was noticed that the slightest trauma produced certain spots of ecchymosis. In January, 1904, she had a severe epistaxis lasting several hours; this recurred at intervals of about one week, for about three months. In December, 1904, she had an attack of so-called "brain-fever," which the doctor thought possibly might have been due to a cerebral hemorrhage. Five months ago she menstruated profusely but not since. She now occasionally had nose bleeds which were readily controlled by plugging and styptics. Following the extraction of a tooth she bled profusely for several days. At the same time she also had a hemorrhagic retinitis. The gums were like those of scurvy. The coagulation-time of the blood was about fourteen minutes. In this case there was absolutely no hereditary history. This disease occurred ten times as often in males as females.

Dr. SARA WELT-KAKELS referred to the case of a boy who had hemophilia. There was no history of heredity. When six years old he began to bleed. Three years ago he passed a basinful of bloody urine. He frequently bled from the nose and mouth. After the extraction of a tooth he bled for fourteen hours. The body was simply covered with ecchymoses and the gums looked like those of scurvy.

Dr. GEORGE H. BELL said he had examined the eyes of the girl whose history was reported by Dr. Nicoll, and said she had poor vision when first seen, about 22/100. She had a hemorrhagic neuroretinitis. There was an extravasion of blood all over the retina, and it first looked like a thrombus of the central vein. The patient first got better and then worse. The last time he had examined her she had a 20/20 vision and the blood had nearly all been absorbed. He called attention to the interesting fact that the retina might become diseased when there were any marked changes in the blood itself.

Dr. GEORGE D. SCOTT said that in many cases that he had seen there was the suspicion of a specific disease acquired prior to birth.

A Case of Non-Closure of the Foramen Ovale and Ductus Arteriosus.—Dr. F. L. WACHENHEIM presented this case. The lesion described was discovered accidentally while going through a routine examination of the child. The most interesting feature regarding the case was that the child was not at all cyanotic and there were no reasons to suspect any cardiac lesion.

A Case of Intrauterine Amputation.—Dr. WILLIAM L. STOWELL presented photographs of a boy 20 months old, who was an abandoned infant and, therefore, with no previous history. He had the following deformities: On the right hand the distal phalanx of the index finger was absent; on the middle finger only the distal phalanx remained; the ring finger was amputated about the first phalanx which reached nearly to the bone. The left hand showed all the fingers partly webbed together, of normal length, but the third and fourth had contractions which made them look like little knobs; the second finger was also contracted towards the palm; the thumb was nearly normal. The right leg presented a groove at the lower one-third directed obliquely from within outwards and downwards. The left leg presented a deep groove below the knee with sharply defined edges. On the left side there was a marked talipes varus. The great toe was normal but the others were webbed almost to the tips.

Dr. ELISHA M. SILL reported an instance of the entire left hand missing on a little girl; there was a perfect amputation at the wrist.

The Fat Question in Its Relation to the Production and Cure of Infantile Marasmus.—Dr. HEINRICH STERN read this paper. He said that it was well understood that infantile marasmus was not the result of the same cause in every instance. Food, however, which was physically, chemically, or biologically unfit for the delicate infantile organism was the most common cause of the gastrointestinal disorder preceding the athrepsia infantum. The reader said further that marasmic conditions occurred comparatively rarely in breast-fed children, and that most instances of malnutrition and marasmus were observed in artificially nourished babies. He said that a much neglected factor in infant feeding, a factor which was frequently at the bottom of athrepsia infantum, was the fat-factor, *i.e.* the chemical and physical character of the fatty substances contained in the food of the infant. He said the amount of the fat-aliment had found frequent consideration, its quality and character on the other hand hardly ever. Fat of mothers' milk should, of course, be the physiological fat-aliment of the healthy nursling as it did not yield low fatty acids to the extent of giving occasion to intestinal disturbance and as it was absorbed in quantities guaranteeing normal and continuous development. The fat of cow's milk was liable to vary to a greater extent than that of human milk, being dependent upon the breed and race of the animal, its individual characteristics, its age, how often it had calved, the time of lactation, the hour of milking, etc., but principally, it differed from the fat of human milk on account of its widely discrepant chemical composition. Especially did the fat of the cow's milk differ from that of the human milk on account of its very large amounts, about 10 per cent., of volatile fatty acids. It was evident that a fat-compound consisting of 10 per cent. of volatile acids could not be a rational substitute for a fatty nutrient into the composition of which these volatile acids entered in but comparatively small amounts. The most important of these acids was

butyric acid, the very presence of which in human milk was doubted by some investigators. As the fat of cow's milk always contained such large amount of butyric acid, and as this was the mother substance of the aceton bodies, the milk cream did not represent the ideal type of a fatty nutriment. Furthermore, the occurrence in the feces of absolutely and relatively larger amounts of the fat of the cow's milk than of that of mother's milk was sufficient evidence of the better utilization of the latter. He said further that it would lead him too far were he to take up the aceton question on this occasion. He merely wanted to mention that aceton of supposedly intestinal formation had been frequently accused of being the forerunner of periodical vomiting in children, of infantile eclampsia, etc. The butyric acid in amounts large enough to give rise to such quantities of aceton bodies must have been ingested as such. Hence it was not more than rational than to assume that the real cause of many of the so-called autotoxicoses were nothing less than simple fat-toxicoses. Withdrawal of milk fat, he said, frequently had helped the child wonderfully, especially in all those cases where there existed a distinct gastrointestinal affection. However, the infant could not exist for any length of time without a fatty substance of some kind. This fat, however, must be assimilable and must not contain a high percentage of volatile fatty acids. Yolk-fat was the only fat which exhibited all the good features of an assimilable fat without having any of the pernicious features of the milk-fat. He said that yolks should be substituted for milk-fat. His reasons were the following: yolk-fat in its native state was well-borne by the majority of infants, the so-called idiosyncracy for eggs was due to the white and not to the yolk of the egg; the great absorbability of yolk-fat; the fat-components of yolk-fat, palmitin, stearin, and olein, did not yield any aceton bodies; the large amount of lecithin contained in the yolk; the occurrence of a diastatic ferment in the yolk; the property of the yolk to stimulate the digestive secretions. Yolks, the speaker continued, had hardly ever been extensively tried in pediatric practice. They must be fresh and should be given in very small amounts when beginning the treatment. They should be added to the carefully skimmed milk in doses of about one-quarter of a teaspoonful for each feeding. However, later on, larger amounts of the yolk might be given.

Dr. Louis Fischer said that he had observed instances of athrepsia infantum and that he was not willing to say that all of them were due to excess of fat, to disturbances caused by fatty acids, or chemical results of fat in the body, but that he considered it more likely that the condition was due to improper quantity or quality of the fat. Most cases of athrepsia he believed were caused by faulty assimilation of the fat due to faulty hygiene as well as to faulty feeding. Many cases might be due to disturbances following proteid feeding rather than to the fat *per se*. That disturbance of the gastrointestinal tract due to excess of fat in the food all had seen and it had been noted in breast-fed children as well as others. He had reported several instances in which there was less than one per cent. of fat in breast milk. He had also used the yolk of an egg where it seemed to be well born, but in some instances there was gastrointestinal disturbance after taking it. He did not think it should be given to a child under six months of age when suffering from severe gastrointestinal disturbance. In regard to the presence of fat in the feces being a guide as to the assimilation of fat, he said that he had examined a great many stools and that in most cases, a great deal of fat was excreted and some of the children did not gain in weight when a small amount of fat appeared in the stools.

Dr. Louis C. Ager said that there were a large number of cases which some believed to be marasmus, which were simply cases of malnutrition. There were also a number of cases thought to be due to infection of some kind, which were striking cases of athrepsia or atrophy of certain parts of the intestinal canal; these latter cases would not recover under any kind of treatment. Theoretically, the yolk of an egg seemed a good thing, and it had occurred to him that in some instances it might be combined with buttermilk, but if one considered the subject from the standpoint of the pathological findings, yolk of egg feeding did not seem to be so encouraging. Both in Europe and in this country, it had been stated that athrepsia was due to an acid autointoxication, and again it had been pretty conclusively proven that this was not an acid intoxication at all. There was undoubtedly a large increase in the nitrogen of the ammonia in the urine or some disturbance in liver metabolism. In these cases there was not the ordinary disturbance which was due to aceton or acetonuria or diacetic acid, which was found in true intoxication. When there was a disturbed liver function, there was a diminution in the secretion of bile and a considerable amount of lecithin in the bile. If the organism was secreting less lecithin than normal, he saw no reason for giving more.

Dr. T. S. Southworth said that he saw distinctly fewer cases of marasmus now than formerly, and he thought it was due to better milk supply in this region. He thought that much could be done in these cases by careful feeding. He had neve thought that fat was a causative factor in the production of marasmus. Marasmus might be caused by too strong milk or perhaps by too frequent changes of proprietary foods. He said that he had had great difficulty in getting children to take the yolk of an egg; it seemed to cause gastric disturbance and vomiting. He had given the whites of eggs in marasmus, although he realized that the whites did not contain all the elements of nutrition. In many cases the milk was not to blame; the absorption of fat was poor, and it was necessary to stimulate assimilation. It was not so much gastric digestion as it was intestinal assimilation.

Dr. L. E. La Fetra said that he had tried the subcutaneous injection of fat without much success. He had also tried the yolk of egg, but many instances of abscess formation followed. He then used the yolks by way of the mouth with orange juice, giving the mixture every four or five hours, and there was much to say in its favor. If the child could not take the yolk raw, he cooked it to a powder and then it could be taken without disturbance. He did not attribute marasmus to fat; there was difficulty in the absorption of fat after marasmus began.

Dr. Stern, in closing the discussion, said that he had been misunderstood. He did not mean to say that every case of malnutrition was produced by the non-absorption of fat, but that there was a certain class of cases indirectly due to the non-absorption of the fat. In every case of marasmus he said if one could substitute another fatty compound which would not yield poisonous material in the body, the patient would be benefited without doubt. The yolk of egg should be administered as frequently as the patient would tolerate it. Where all the milk fat had not been removed before adding the yolk, some gastrointestinal disturbance followed. It was rather difficult to remove all this fat from milk. Dr. Stern said he could not give clinical reports of this method of feeding in infants, but that statistics would be forthcoming later.

Important Differential Points in the Diagnosis of Sporadic Cretinism, Mongolism, Achondroplasia, and Rachitis.—Dr. Charles Herrman read this paper. He said that at first sight it might seem remarkable that conditions so widely different in their pathology should offer difficulties in the way of differential diagnosis. These conditions offered a striking illustration of how different causes acting in different ways might produce similar results. In defining these terms Dr. Herrman said that a number of different conditions had been grouped under the head of fetal rickets. The term should be dropped or applied only to those very rare cases in which the rachitic process developed in utero and ceased before birth. The rachitis considered in this paper was the ordinary form so frequently seen in infants and children. Under cretinism he considered only the sporadic cretinism or infantile myxedema. By mongolism he would have understood that form of congenital idiocy

of unknown origin in which the patient presented the Mongolian slant of the eyes. Under achondroplasia or fetal chondrodystrophy he considered the condition as it occurred in infants and children. The reason that all the cases of one group resembled each other was that certain features were so accentuated. In sporadic cretinism it was the depressed bridge of the nose, the puffy eyelids, thick lips, prognathous jaw, and idiotic expression. In mongolism it was the peculiar slant of the eyes. In achondroplasia the marked disproportion between the head, trunk and extremities. The development of the nasal and superior maxillary parts was dependent upon the growth at the base of the skull. When there was a premature synostoses of the tribasilar bones or a lack of growth of the cartilaginous structures between the bones, the nasal and superior maxillary arts were not pushed forward sufficiently, so that a depressed nasal bridge resulted. This might also occur as the result of insufficient growth of the cartilaginous structures anterior to the tribasilar bones, without any change of the normal development of the bony or cartilaginous structures at the base of the skull. In chondrodystrophy either of these conditions might be present; in sporadic cretinism there was usually in insufficient growth at the base of the skull; in mongolism there was probably an arrest of development of the structures at the base of the brain. Mongolism and chondrodystrophy were always congenital conditions and the characteristic features were evident at birth. Sporadic cretinism was often a congenital disease in that the thyroid gland was abnormal and its secretion defective from birth, though the symptoms might not appear immediately. In all of these conditions the patients were undersized, though this was most marked in cretinism and achondroplasia. In all there was a deviation from the normal growth at the junction of the ephiphysis and diaphysis. In rachitis and mongolism all the parts were nearly uniformly affected while in sporadic cretinism the extremities were somewhat more affected and in chondrodystrophy the extremities were almost exclusively affected, the growth of the head and trunk remaining nearly normal. All these children began to walk late, showed lack of muscular power and of the power of coordination. In cretinism, mongolism, and rachitis there might be anemia. The anemia of cretinism had often a yellowish or greenish hue, with marked reduction in the percentage of hemoglobin. In rachitis we had all grades of Von Jaksch anemia. A marked persistent subnormal temperature, reacting immediately to thyroid treatment, was characteristic of sporadic cretinism. These patients were cold, cyanotic, with slow pulse, defective heat production and radiation, and torpidity of all the vital processes. In mongolism the temperature was sometimes subnormal, but never so marked or persistent as in cretinism. Uncomplicated cases of rachitis and chondrodystrophy had a normal temperature. In cretinism the skin often presented a characteristic myxedematous infiltration. In cases of infantile myxedema and chondrodystrophy there was often a redundancy of the tissue about the legs. In all of these conditions there was delayed closure of the fontanelles. In rachitis the head was large and square, with prominent frontal and parietal bones. In mongolism the head was brachycephalic, the anterioposterior and lateral diameters being nearly equal. The occiput was flattened and frequently the temples hollowed. The sutures as well as the fontanelles remained open much longer than normal. In cretinism the head was small but presented nothing characteristic. The hair as against mongolism, was coarse, dry, and scanty. In chondrodystrophy the head was relatively large. Adenoid vegetations were frequently present in these conditions on account of the depressed nasal bridge and high arched palate. The nose is chondrodystrophy had a bulbous end. In cretinism the tongue was increased in size, and protruded partly. In mongolism the tongue was not enlarged, though on the dorsum the fungiform papillæ were increased in size, and the tongue was sometimes fissured. The high-arched palate was especially frequent and marked in mongolism. The teeth appeared late in all, but especially so in cretinism. In cretinism the rings of the trachea could be distinctly felt. In rachitis the chest showed characteristic changes: the rosary, due to an inreased growth of cartilage at its junction with the osseous portion of the rib, a prominent sternum, and Harrison's groove. In chondrodystrophy there might be beading of the ribs, otherwise the chest was well formed, of normal dimensions, and in striking contrast to the short extremities. Curvature of the spine, kyphoscoliosis, was present in rachitic cretinism. In chondrodystrophy there was usually marked lordosis in the lumbar region. In all these conditions the extremities, especialy the lower, were shorter than normal. This was especially marked in chondrodystrophy. In all, but especially in cases of mongolism, the joints were extremely lax. In cretinism the hand was flat and spadelike, cold and cyanotic, the fingers short and stumpy, and the radiograph showed a delay in the appearance of the ossification centers, a point which would make clear a diagnosis in a doubtful case. In well-marked cases of rachitis the hand was long and narrow with the thumb flexed. The fingers showed a peculiar beaded appearance. In chondrodystrophy the hand was small and square, the fingers of nearly equal length with blunt ends. The radiograph showed short, thick metacarpal bones with large heads and a normal or premature junction of the epiphyseal ends. The hand of mongolism approached more nearly to the normal. In cretinism the genitals were often unusually large and the skin of the scrotum thickened, though sexual power was deficient. In rachitis there was often profuse sweating, while in cretinism never. A persistent obstinate constipation in a breast-fed infant dating from birth, was characteristic of sporadic cretinism. This would disappear under thyroid treatment. In rachitis the intelligence was only retarded in so far as the children did not go about and mingle with others so early. In chondrodystrophy the intelligence was not markedly affected, though it was not normal. Cretins untreated were sluggish, apathetic or idiotic. The earlier treatment was begun the better the chances for an approach to normal intelligence. In mongolism there were all grades from the mildest form of imbecility to complete idiocy. These patients were usually lively and restless. He had noted no improvement, however, under thyroid treatment. The prognosis in uncomplicated rachitis was good; in chondrodystrophy if they survived birth they seemed to grow stronger as they grew older, but remained undersized. In sporadic cretinism if treatment was begun early, the mental as well as the physical improvement was pronounced. Cretins were less resistant to pulmonary disease. Mongolian imbeciles were also especially prone to pulmonary diseases. In chondrodystrophy the principal change was a defective formation of the rows of cartilage cells, which prevented growth in length. In rachitis the enlargement of the ends of bones was due to an abnormal development of the epiphyseal cartilage; in chondrodystrophy, to a periosteal overgrowth. Microscopically, in rachitis the proliferating zone between the bone and cartilage was wider and more vascular. The bowing of the bones in rachitis was due to softening of the bone; in chondrodystrophy, to peculiarities in the joint, or to resistance offered to growth in length by the periosteal intrusion. In rachitis all the bones of the skull were affected, while in chondrodystrophy only those of the base. In sporadic cretinism there was an absence of atrophy or sclerosis of the thyroid, and a delay in the appearance of the ossification centers. Treatment with the thyroid extract was specific only in cases of cretinism.

Dr. P. W. Nathan said that within recent years the pathology of achondroplasia had been studied by Kaufmann and his pupils, and that these cases had been divided into three classes, one of which showed a disease of the primordial cartilage. There might be a hyperplastic process in which the cartilage was uniformly enlarged, or again there might be another change in which the cartilage became softened. The disease probably began at an early age of fetal life, and ran more or less of a rapid course, with the result that there was more or less of a complete cessation of the cartilaginous growth; and instead of remaining in the cartilaginous

state underwent ossification, which precluded further growth and this was the cause of dwarfism. The same condition of affairs took place at the base of the skull which developed, as all knew, from cartilage and not from membrane. The same changes occurred here as occurred at the ends of long bones and a complete synostosis was noted. When this synostosis occurred at this site growth discontinued while the vault of the skull continued to grow. A particularly striking feature was the retraction noticed at the root of the nose, caused by the cessation of growth at the base of the skull. He said Kaufmann had claimed that in a certain percentage of the cases the bones anterior to the ethmoid and sphenoid, instead of ceasing to grow, became hypertrophic, which made up for the deficiency of growth of the bone posteriorly, and there was, as a result, no retraction at the root of the nose at all. Therefore, one might see a flattened nasal region. A diagnostic point in chondrodystrophy was a lack of uniformity in the length of the limbs and trunk, the legs always remaining behind in size. Again in chondrodystrophy, there might also be a disturbance in the growth of the cartilage in the bones of the trunk and bodies of the vertebra besides the other dystrophic changes.

Dr. L. Pierce Clark showed some pictures of ancient historical monstrosities, idiots, Eygptian gods, etc., which he had shown in connection with a paper recently read by him before the New York Psychiatrical Society.

NEW YORK ACADEMY OF MEDICINE.

Section on Medicine.

Stated Meeting, Held April 18, 1905.

Dr. Charles H. Lewis in the Chair.

Report of a Case of Cerebrospinal Meningitis.—Dr. Charles H. Lewis reported this case in which the points of interest were (1) the rapid course of the disease and (2) the source of the infection. If one started from the first symptom of the illness, which was in no way diagnostic in particular, the duration of the disease, from chilly feeling to death, was 29 hours; but if one counted from the appearance of characteristic symptoms from the time the clinical picture at all resembled the real disease, the duration would come well under twenty hours. As relevant to the source of the infection, it was well to state that the patient had not been off the floor on which his room was located for six months. During the past year, two cases of cerebrospinal meningitis had been treated on this floor. The first occupied a room directly opposite to this patient's room. The second occupied a room opposite a corridor in which this patient was daily wheeled, and where he spent a good part of the day. The first patient was admitted March 15 and died in two days. The second was admitted April 5 and died in twenty-four hours. If the infection came from either of these two cases, it would seem that individual susceptibility must play about the entire rôle in infection by the diplococcus intracellularis meningitidis.

Dr. J. Finlay Bell reported a case of cerebrospinal meningitis in which the pneumococcus was the infecting agent; this was found in pure culture.

Pernicious Anemia with Exhibition of Case.—Dr. Theodore C. Janeway presented this patient because he had had him under his personal observation for five years, during three of which he had been in excellent health. The history of the case dated back even nine months prior to that time. In looking over the literature he was impressed with the fact that so few cases had been followed any length of time, very few having been observed even as long as one year after discharge. The patient he presented was a man, 47 years old, who came to him at the University and Bellevue Hospital clinic in March, 1900. He had a good family history. He had specific disease 20 years before. The only previous history he gave was that of having had malaria when 11 years old, and typhoid fever 13 years ago. This was followed by jaundice which persisted for two or three years. He lost weight from 165 to 87 pounds. In 1899 he began to have diarrhea, ten or twelve passages a day; he became yellow and remained so until he saw him at the clinic. There was no blood or mucus in the stools. There was no pain. When first seen he was moderately emaciated and he had a slight jaundice. The liver was not enlarged, but there was noted a nodule on the lower border. He also had a palpable spleen. The case was first considered to be one of gumma of the liver and he was treated with bichloride and the iodides under this assumption. On that treatment the jaundice disappeared, but a rapid anemia developed within two weeks. At this date, April 16, 1900, there was 40 per cent. hemoglobin and 2,333,000 red cells. He was placed upon arsenic and sent to the hospital. No parasites were found. He made a fairly rapid recovery, gaining 10 pounds and on May 19, 1900, the hemoglobin was 62 per cent., 3,488,000 red cells and 8,500 white blood cells. Another examination made February 9, 1901, showed 75 per cent. hemoglobin, 3,376,000 red cells. He then began to have exactly the same kind of diarrhea that he had before, became tired on exertion and again came to the clinic with a dilated heart, palpable spleen, slight subcutaneous edema, but with no retinal hemorrhages. On December 31, 1901, there was found 40 per cent. hemoglobin, 1,756,000 red cells and 4,200 white blood cells. On January 13, 1902, there was 50 per cent. hemoglobin, 1,956,000 red cells and 2,200 white blood cells. There was no hydrochloric acid or pepsin in the gastric juice. He was given calomel purges and irrigations of the colon in the knee-chest position, and he again made a rapid recovery. On January 23, there was 63 per cent. hemoglobin, 2,524,000 red cells. On March 4, there was 75 per cent. hemoglobin and 3,444,000 red cells. On December 4, 1902, there was 85 per cent. hemoglobin and 3,800,000 red cells. On April 14, 1905, there was 80 per cent. hemoglobin and 3,432,000 red cells. The blood picture to-day showed a deficiency in the red cells. The patient was in perfectly good condition now, nearly six years after he had his primary pernicious anemia.

Report of a Case of Hemophilia.—Dr. Harlow Brooks reported this case mainly on account of certain observations that had been made concerning the blood which he thought might have a bearing on the true nature of the disease. This patient had been under his care for two years. He was 21 years old, a clerk, with a poor family history so far as the hemophilia went. For two generations the males of the families were the subjects of severe hemorrhages at times. Subcutaneous hemorrhages were often noted. The mother of the patient was alive and was 43 years old, mother of five children. At this early age the menopause had become established. The father was the subject of occasional nose bleeds. The family seemed to be very sensitive regarding the subject of bleeding. The patient was one of five children. Two of them died before the age of nine months from incontrollable hemorrhages, both having been under the care of very good men. One brother was the subject of very severe bleeding following the most trifling injury. At the age of 16 he was supposed to have an acute miliary tuberculosis starting in the knee joint, but this diagnosis was not verified by autopsy. A sister, now 14 years old, was always well except for tuberculous glands in the neck; she apparently had no tendency to unnatural bleeding. The patient had his first bleeding when nine months old, when he bled for twenty-one days. A second attack occurred when he was 18 months of age, and was uncontrollable for fourteen days. Nothing used seemed to have any effect. He finally began to have profuse hemorrhages from the gums. When three years old the chief seat of the hemorrhages was the nasal mucous membrane. Now such hemorrhages do not last more than two or three hours and seem to respond readily to ad-

renalin. Examination of the sputum was negative. The pulmonary changes noted he believed were due to hemorrhages within the lungs; this condition was often diagnosed as tuberculosis. The heart was slightly enlarged and the arteries were soft, but evidently not the seat of any arteriosclerosis. The muscles were wasted, especially after any severe hemorrhage. When the fingers were pressed in the skin deeply, blue spots of ecchymosis would develop. Now the joints showed the sites of the chief seats of hemorrhage especially the left wrist and left knee. Orthopedic surgeons had diagnosed them as being tuberculous. The *x*-ray examination showed the ends of the bones to be natural so far as could be told. The urine contained at times large quantities of blood. With Janeway's instrument the blood pressure was, on an average: systolic, 112; diastolic, from 60 to 70. The blood after severe hemorrhages showed such changes as occurred in moderate secondary anemia. The hemoglobin was 60 per cent., red cells 3,500,000 and leucocytes 6,000. Clot formation occurred in from six to seven minutes. The boy had been placed on colcium chloride in the hope of increasing the coagulability but without result. He was placed on ergot hypodermically, and this gave a slight temporary change, but soon it passed away. When there was bleeding from kidney, ergot did well for three or four hours, when the bleeding would return. Adrenalin usually controlled the hemorrhage when given continuously. This case he said represented fairly clearly that hemophilia was not due to any deficiency in the blood itself. There must be some deficiency in the quality of the blood-vessels. The amount of blood lost now was less than that of last year; each year the amount lost seemed to be less than the preceding year. Therefore, in this case, the prognosis should be fairly good.

Analysis of Forty Cases of Arthritis with Special Reference to the Diagnosis of Gout and Rheumatism.—Dr. Chas. C. Ransom read this paper. He said that the differential diagnosis of gout, rheumatic arthritis and gonorrheal arthritis would be a comparatively simple matter if these cases were seen in their initial attacks and if these happened to occur in the typical manner, but it was the misfortune of the clinician to see them in various stages of development, when many joints were involved and when none of the rules that we were taught to measure them by seemed to apply. He endeavored to demonstrate the difficulties of diagnosis and to show how vastly different from the book cases many of them were, as regarded their mode of onset, the joints first attacked and those ultimately affected, and to tabulate them in reference to these features. In 40 cases of arthritis which he had analyzed, 6 were of arthritis deformans, and these he omitted as not coming within the scope of the paper. The remaining 34 cases were divided as follows: gout, 20 cases; rheumatic arthritis, 6 cases; gonorrheal arthritis, 7 cases; septic arthritis, 1 case. With the exception of one case of rheumatic arthritis, all these cases were polyarticular. With reference to the joints implicated he found the metatarsophalangeal joint of the great toe affected in 40 per cent., the knee in 25 per cent., ankles in 15 per cent., instep in 5 per cent., shoulder in 5 per cent., hip in 5 per cent., phalanges in 5 per cent. These figures were at variance with those given by most writers. Ewart calls attention to a rare case in which the small joints were not first affected, whereas 55 per cent. of these cases had their beginning in the large joints. Of the joints ultimately affected the disease was limited to the small joints in 15 per cent., to the large joints in 20 per cent., and affected both large and small joints in 65 per cent. of the cases. Here were found more cases limited to the large than to the small joints. Of the rheumatic cases the joints first affected were the ankle in 50 per cent., the knees in 33 per cent., and the hand and wrist in 16 per cent. Of the joints ultimately affected the disease was limited to large joints in 50 per cent., to small joints in no instance, and affected both large and small joints in 50 per cent. In none of these cases were the great toe joints involved. The small joints involved were those of the upper extremities. The cases of gonorrheal arthritis gave the following: Joints first involved, hand and wrist in 43 per cent., knees in 28 per cent., ankles in 14 per cent., and great toes in 14 per cent. Of the joints ultimately involved in gonorrheal arthritis it was limited to the large joints in 43 per cent., to the small in no case, and affected both large and small joints in 67 per cent. Among these cases the vertebræ were affected in two instances, temporomaxillary joint in one instance. It could readily be seen that from the physical condition alone in a large number of these cases a diagnosis would be impossible. This was especially true where gout affected the large joints. Dr. Ransom cited the history of the onset in four cases as illustrative of his statement that it was much easier to diagnose these cases in the beginning than later and also to show that the classical picture might be wanting even at that time. He cited one case as illustrative of the necessity in all cases of arthritis to make careful inquiry into the presence of urethral or vaginal discharge, and when any existed to supplement inquiry by personal examination. Of the four acute cases cited two were in their mode of onset and history sufficiently obscure to make a wrong diagnosis possible. If in 50 per cent. of acute cases and 65 per cent. of chronic cases of arthritis it was impossible to make a correct physical diagnosis, we might ask what chance of relief there was for these sufferers. Fortunately, we had two remedies which aided us without working any injury to our patients, and which would enable us to make a correct diagnosis within a few days. He referred to salicin in rheumatism and colchicin in gout. He gave the following conclusions based upon several years' experience with these drugs: In true rheumatic inflammations salicin was a specific. The average duration of an attack of acute rheumatic arthritis, when treated with salicin, was 50 hours. To get its specific effect it must be administered in five doses, at least 20 grains every hour. It was non-toxic and non-irritating, and large doses were followed by no ill effects, consequently it was vastly superior in these affections to salicylic acid or any of the salicylates. It could be used in subacute and chronic cases with equally good effect, though its action was not so prompt. It had very little, if any, effect in arthritis due to gout, and was, therefore, of great value in differentiating these conditions. In a doubtful case of arthritis after 72 hours' treatment with salicin, if the symptoms had not materially lessened, it was safe to assume that the disease was not rheumatic. In true gouty arthritis colchicin was a specific. Its effect in acute cases of gout was quite as prompt as that of salicin in rheumatism. It was also of great value in subacute and chronic conditions. In large doses it was a toxic and a decided irritant to the gastro-intestinal tract, but to get its full effect it was not necessary to carry it to the point of active purgation. In heart disease and nephritis it might be used with safety. Colchicin had absolutely no effect upon either rheumatic or gonorrheal arthritis.

Dr. Wisner R. Townsend believed that the *x*-ray examination gave no data of value in differentiating between rheumatic and gonorrheal joint affections. But in the more chronic cases there were very valuable data to be had. The treatment in all cases seemed to be immobilization of the joint involved; this not only would tend to relieve the symptoms, but it would prevent any complications which so often followed, *i.e.* ankylosis or false positions.

On the Impossibility of Differentiating So-called "Paratyphoid" from Typhoid Fever Except by Bacteriological Examination of the Blood.—Dr. Warren Coleman presented this paper, in which he endeavored to prove that paratyphoid and typhoid fevers were identical clinically and that they could be differentiated only by the recovery of the bacillus concerned from the blood. He had expressed the opinion that there was as great a diversity among the different types of typhoid fever as between typhoid fever and paratyphoid infections and that the idea of specificity of typhoid fever should be abandoned and the scope of its etiology should be broadened to include

B. alkaligenes fecalis, B. typhosus, B. paratyphosus, and certain numbers of the paracolon group. Further experience had convinced him of the correctness of this opinion. He included *B. alkaligenes fecalis,* lying just without the group on the typhoid side, because it had produced typhoidal symptoms. The other members of the group were *B. typhosus,* the paratyphoid bacilli, which were not identical either in biological or serum reactions, the paracolon bacilli, which likewise differed among themselves, *B. enteritidis,* consisting of different strains, *B. pstittacosis,* and *B. coli communis.* All of these had produced diseases characterized by typhoidal symptoms, with the possible exception of *B. coli communis.* These were distinct diseases from the bacteriologist's standpoint, but were not necessarily clinical entities. The pathological anatomy of the cases of infection which had come to autopsy had differed from that of typhoid fever. Peyer's patches had escaped, though four of six cases showed intestinal ulcers. A positive clinical diagnosis of even a typical case of typhoid fever was beset with difficulty, as no case was typical until it had finished its course. Some of the reported cases of paratyphoid infection had been described as typical attacks of typhoid fever. Some had been mild and some severe. There had been no symptom of typhoid fever constantly absent and there had been no symptom constantly present that we might not get in typhoid fever. All that it could claim as a distinct disease was that the cases were milder and of shorter duration, that the mortality was lower, and that some complications, as myositis and purulent arthritis, were more frequent. He thought that the majority of short duration cases were caused by some member of the typhoid-colon group of bacilli. The time had even come when we must take into consideration the possibility of the occurrence of primary systemic infection by the colon bacillus itself. The argument that cases of paratyphoid fever had been of short duration would not distinguish them from typhoid clinically. In a number of cases of short duration the diagnosis was placed beyond dispute by the recovery of typical typhoid bacilli from the blood. One lasted ten days and another fourteen, and their symptoms corresponded perfectly with those of some of the reported cases of paratyphoid. A negative serum reaction in a case of suspected infection by some member of the typhoid colon group meant only that the agglutins had not developed in sufficient quantity to give the reaction. Variability in the time of appearance of the reaction was well known. Even a positive reaction with a paratyphoid bacillus at higher dilution than with *B. typhosus* did not prove that this bacillus was the cause of infection. Grünbaum and Jolly had recently published a paper on the inconclusive nature of the results of the agglutination reaction in cases of typhoid fever. He tested the reactions in the blood of positive typhoid cases against paratyphoid bacilli and obtained agglutination in 70 per cent. of the cases examined. In some cases the paratyphoid bacilli agglutinated at higher dilution than typhoid bacilli. In 55 per cent. of the cases a colon bacillus reacted with the sera and *B. enteritidis* (Gaertner) in 22 per cent. He said this only confirmed what had been demonstrated some years ago, that the reactions of the typhoid-colon group were special and not specific. It was necessary to exercise caution in drawing conclusions even from positive reactions. The diagnosis of paratyphoid infections concerned the bacteriologist more than the physician. A successful bacteriological examination of the blood became then the only final criterion of diagnosis in the differentiation of infections by various members of the typhoid-colon group of bacilli. The following conclusions were drawn: (1) That paratyphoid infections could not be distinguished from typhoid fever except by the recovery from the blood of the bacillus concerned, and its proper identification. (2) That the present state of our knowledge made it advisable to consider typhoid fever, clinically, as a disease which might be caused by several members of the typhoid-colon group of bacilli. (3) That the term "paratyphoid fever" was not only unnecessary, but misleading.

Drs. W. Gilman Thompson, S. J. Meltzer, Morris Manges, James Ewing, William H. Park, and E. Libman discussed this paper.

New Instruments.

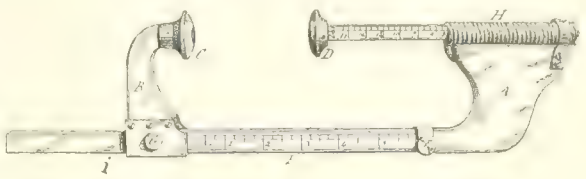
A NEW TENSION METER.

By A. G. Field,

Des Moines, Iowa.

In atrophy of limbs from paralysis or traumatic injury it is customary to grasp the limb and depend upon the sense of pressure to determine the extent of softening.

The accompanying illustration shows an instrument devised to determine with mechanical precision the extent or degree of softening by measured resistance to pressure. It is applicable in diagnosis and prognosis, and also in normal athletic development. It consists of a shaft, upon one end of which is mounted a coiled wire spring, *h*, the strength of which is ascertained and represented in pounds by numbers upon the rod extending through the spring which carries the knob, *d*. The other end of the



shaft carries the sliding arm, *b*, with knob, *c*. The thin brass scale, *e*, is graduated in inches. It is pivoted to the sliding band with set screw *f*, at one end, the other passing through the clasp of the arm, *b*, terminates with a clip, *i*, behind the clasp, to hold the arm.

For use hold the instrument in the right hand by the pistol-like handle, *a*, with knobs up, both set screws *f* and *g* loose, and adjust the knobs loosely to opposite sides of the limb to be examined. Secure the sliding arm *b* in position by tightening the set screw *f*. The muscles being relaxed, slide the arm *b* along the scale one inch and tighten the set screw *g*. The rod carrying the knob *d* gives the force in pounds required to make the one inch indentation in the limb, of which make note. Without moving the instrument, require the subject to contract the muscles of the limb. The rod will give the expansion force in pounds resulting from the muscular contraction, of which again make a note. We thus have the measure of resistance in both the passive and active condition of the muscles.

While a paralyzed limb registers very low, proportioned to the extent of atrophy, that of an athlete will register up to or possibly beyond the capacity of the instrument.

The Sterilization of Women.—Reifferscheid says Küstner has recently reported two cases in which he performed vaginal fixation of the uterus, combined with sterilization by the excision of a short piece of each tube at its uterine extremity and shallow excision of the uterine stump. Notwithstanding these apparently radical procedures, both patients became pregnant, and, owing to the nature of the uterine operations that had been done, abortion had to be induced. The author's case was that of a woman at whose second cesarean section a portion of each tube was regularly excised, but some years later she returned pregnant and indignantly presented a written statement given to her on her discharge from the hospital, to the effect that further conception would be impossible. It is apparently essential in order to prevent such accidents to remove the entire length of each tube and to excise a deep wedge from each uterine cornu.—*Zentralblatt für Gynäkologie.*

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending June 3, 1905:

	Cases	Deaths
Measles	727	17
Diphtheria and Croup	320	27
Scarlet Fever	152	14

Typhoid Fever	38	4
Cerebrospinal Meningitis	71	60
Typhus Fever	.....	.....
Yellow Fever	.....	.....
Cholera	.....	.....
Totals	1,815	264

Digestive Disturbances.—J. Henry Schroeder states that digestive disorders may be the result of organic disease of the digestive organs, of functional disturbance, either primary or secondary, or of faulty diet. They may be associated with psychic conditions which have a depressing influence upon the body functions. When these disturbances are present, there does not necessarily exist any interference with the chemical process of digestion, either in the stomach or intestines, for the disorder may show itself chiefly by subjective symptoms, such as pain and discomfort. Examination of the patient may prove that the trouble is intestinal, or a reflex manifestation of disease or anomaly in other organs. Chronic digestive disorders that are the object of special observation usually occur in adults. However, children are not exempt. In childhood, the diet is more easily controlled than it is later, and the environments are better, thus urgent symptoms do not always arise. The writer describes a case of chronic gastritis with atony and dilatation in a child. Treatment consisted of lavage and withdrawal of all food for twenty-four hours. Later, lavage and properly regulated bland food were given. The stomach symptoms rapidly subsided. Functional disturbances of the stomach, which are similar to those associated with organic diseases, are classified as neuroses. Disturbances of the secretory function of the stomach, due to neuroses, according to the writer, may, or may not, be accompanied by gastric symptoms. A hypersecretion of acid or gastric juice may be associated with very distressing symptoms. "Heartburn" is familiar to all. At some times the symptoms are very suggestive of gastric ulcer. Subjective symptoms in these troubles may be suggestive, but conclusions concerning the case cannot be based upon them alone. The methods of careful examination which have been so carefully worked out should never be neglected.—*Lancet-Clinic.*

An Undescribed Form of Ulceration of the Large Intestine, Probably of Amebic Origin, Causing in Some Cases Abscess of the Liver.—T. G. Mugliston and G. D. Freer describe the condition of patients suffering from this affection as follows: There may be little or no fever in uncomplicated cases. The patient as a rule states that he has not felt well for a week or more, and that he has undefined pains in the abdomen, and that his motions are more frequent than usual. The temperature is generally about 99° in the morning and 99.5° at night. It some cases it is normal all day. The stools are not offensive, but are full of jelly-like slime, with a few streaks of blood. Some tenderness exists over the ascending and transverse colon. If the patient stays in bed, and adheres strictly to a milk diet, the motions will generally become healthy within three weeks. If, however, he keeps about, he is finally attacked by rigors, accompanied by a rapid rise of temperature to 104° or 105°. Severe pain, which increases day by day, is felt over the hepatic region, and other symptoms of liver abscess develop. Although an abscess may be present at this stage, it may be very difficult to find, and if found, difficult to treat satisfactorily. The writers believe that these cases are more common than is supposed. Some may even be of the ambulatory type and entirely escape notice. All of the noticed cases have been so far in Europeans. The writers describe two cases, both of which were fatal. The dysenteric condition was associated with liver abscess, and toward the end with uncontrollable hemorrhage from the bowel. At the post-portem examination, instead of the ragged, irregular ulceration affecting a considerable part of the large intestine as would have been expected, there were present in the cecum and adjacent part of the ascending colon a few symmetrical ulcers, round or oval in shape, with raised rounded edges somewhat undermined. They resembled typhoid ulcers of the small intestine. Examination of the liver of the second patient after death revealed the presence of amebas in the necrosed tissue at the edge of the abscess.—*The Journal of Tropical Medicine.*

Protection Against X-Rays.—It has been found by Barrett that certain substances or bodies of high molecular weight are opaque to the rays. He proposes gloves with a space filled with iodoform as lighter than those leadlined and quite as efficient. It would seem, however, that the odor might be almost as objectionable as a mild burn.

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ending June 3, 1905:

THE CARBON FACTOR IN GOUT: "HYPERPYREMIA."

BY FRANCIS HARE, M.D.,

LONDON, ENGLAND.

LATE CONSULTING PHYSICIAN, BRISBANE GENERAL HOSPITAL; VISITING PHYSICIAN, DIAMANTINA HOSPITAL FOR CHRONIC DISEASES, BRISBANE.

IF we take as an average normal diet the mean of Moleschott's, Ranke's, Pettenkofer's, and Voit's diets for a man in ordinary work, we obtain proteid 4.31 ounces, fats 3.35 ounces, and carborydrates 11.71 ounces (B. Yeo).[1] One-third of the proteid (1.43 ounces), containinng a little carbon and practically all the nitrogen, is rapidly discharged as urea (M. Foster).[2] The remaining two-thirds of the proteid (2.88 ounces), together with all the fats and carbohydrates, contain carbon but no nitrogen. Thus, 93 per cent. of the total food supply is non-nitrogenous: neglecting the hydrogen, we may refer to it more conveniently as "carbonaceous."

In ordinary circumstances, the carbon income of the blood depends upon the carbon intake and upon the efficiency of the functions of digestion and absorption (oral, gastric, and intestinal)—functions which it will be convenient to speak of conjointly as "carbonization."

In ordinary circumstances, the carbon expenditure of the blood comprises combustion, which is a catabolic function of the nitrogenous tissues; various constructive processes, such as fat formations, uterogestation, and the formation of certain secretions (milk, bile, sebum, etc.), all of which may be classed as anabolic functions of the nitrogenous tissues; and a certain amount of direct loss in the physiological process of menstruation. All these processes may be spoken of collectively as "decarbonization,"* and separately as catabolic, anabolic, and hemorrhagic decarbonization.

We may fairly suppose that a near approach to uniformity in the composition of the blood as regards its contained carbonaceous material is a physiological essential; and such must depend upon accuracy of balance between carbonization and decarbonization. Such accuracy is always assumed. It is said, for example, that carbonaceous material absorbed but not utilized in the development of force and heat, is of necessity stored extravascularly mainly in the form of fat; and, conversely, that carbonaceous material absorbed but not stored extravascularly, is of necessity oxidized and excreted as carbonic acid. This assumption implies an invariable adequacy of the physiological functions concerned. But it seems a larger assumption to postulate an invariable adequacy than an occasional inadequacy. And a long consideration of the laws of carbonaceous metabolism (in so far as they are known) has served to convince me that not infrequently the metabolic balance referred to is inaccurate—that in many circumstances, decarbonization is prone to fall behind carbonization, with the result that carbonaceous material accumulates in the blood to an ultra-physiological or pathological degree. The à priori probability that this occurs at times seems to me extreme, but the arguments in support cannot here be considered through lack of space. To the hypothetical blood state implied, I have for convenience applied the term "hyperpyremia" (Greek πυρεία-fuel). Consistently we may use the term "pyremia" to denote the condition of the blood which contains carbonaceous material not in excess of the physiological capacities of the organism.

*The term decarbonization has been applied to the excretion of carbonic acid from the blood through the lungs. In this article, it is of course used in a different sense, namely, to include all the processes whereby the blood is relieved of the unoxidized carbonaceous material constantly being supplied from the alimentary canal.

The chemical constitution of the hyperpyremic load is of course matter for surmise. It may consist of a mere quantitative increase of the compounds which constitute pyremia; it may consist of a complex condition including quantitative departures from pyremia; and it may vary in different cases. All we have a right to suppose is that the hyperpyremic load is primarily carbonaceous. But it is certain that hyperpyremia is not identical with hyperglycemia. The latter is stated to lead in all cases to glycosuria; and glycosuria, as I shall point out, is for the most part antagonistic to the presumed clinical manifestations of hyperpyremia.

It is inconceivable that a progressively increasing hyperpyremia can continue indefinitely. We have to consider therefore by what means the increase is checked or the condition dispersed. It is useless to search in the domain of physiology, since the term hyperpyremia implies the failure of physiological action. Manifestly we have to prosecute the search in the domain of pathology.

The number of pathological processes which would be capable of dispersing hyperpyremia is large. But it will suffice to refer to a few, namely, bilious attacks, migraine, gastralgia associated with anorexia, asthma, major epilepsy, and acute articular gout. All these recurrent processes can be shown to arise in some cases under conditions which would tend to cause hyperpyremia, and it can be shown that they are susceptible in many cases of mitigation, in some cases of complete suspension, by conditions which would be capable of dispersing hyperpyremia. Further, it can be shown that they themselves tend to disperse hyperpyremia. To this end they operate in different ways. Bilious attacks, migraine, and gastralgia, associated with anorexia, operate mainly by means of restriction of income. Asthma, major epilepsy, and acute articular gout operate mainly by means of increase of expenditure; the first two through exaggerated muscular exertion, the last through pyrexia.

All these affections, therefore, may be regarded provisionally in some cases as pathological capacities—as pathological reinforcements of inadequate physiological function. We could not indeed term them all pathological *de*carbonizing processes, because, as pointed out, some operate, not through increase of expenditure, but through restriction of in-

come. We might, however, group them all under the more inclusive term "pathological *a*carbonizing processes."

The evidence in support of this conception is in the main clinical, and therefore circumstantial. But it is extremely large, covering as it does the literature of medicine from the time of Hippocrates to the present day. In a work shortly to be published,[3] I have extracted and endeavored to arrange in logical sequence a small portion of this evidence. To attempt more would necessitate at least one lifetime and a work of encyclopedic dimensions.

Meanwhile the evidence which applies to acute articular gout may be briefly sketched. This, as will be seen, consists of long known and well authenticated observations looked at from a new standpoint and rearranged accordingly.

Evidence that Acute Articular Gout Depends Upon Hyperpyremia.—This may be generalized: Conditions presumably tending to cause hyperpyremia whether through increase of income or through restriction of expenditure, are favorable to the development of gout and may increase the gouty manifestations; conditions presumably tending to disperse hyperpyremia, whether through restriction of income or through increase of expenditure, are hostile to the development of gout, and may succeed in diminishing or dispersing the gouty manifestations.

Food and Dietetic Treatment.—As already stated, the carbonaceous income of the blood depends upon the carbonaceous intake and upon the efficiency of the carbonizing functions. The efficiency of the carbonizing functions depends on the efficiency of all functions, and fundamentally upon the proteid intake (Parkes).[4] As is well known, "when an animal is fed simply on non-nitrogenous food . . . the food rapidly ceases to be digested and starvation ensues" (M. Foster).[5] Hence the diet most certain to cause hyperpyremia would contain proteid in amount sufficient to maintain efficient the carbonizing functions, together with an excess of carbonaceous material. Such would constitute not an almost purely animal diet, nor an almost purely vegetable diet, but a heavy mixed diet, just such a diet indeed as has always been regarded as the worst for gout. Conformably, Woods-Hutchinson has recently pointed out that "an excess of starches and sugars with a moderate amount of nitrogenous elements in the diet will promptly produce gout in susceptible subjects;"[6] and that the only lower mammal in which gout occurs is the omnivorous pig. It is needless to multiply evidence of the influence of a heavy mixed diet in gout, such being generally admitted.

The prejudicial influence on gout of alcohol *per se* is disputed. But all are agreed that alcoholic beverages containing soluble carbohydrates are especially harmful. Malt liquors are now condemned by all. Port wine is notoriously bad: it contains glucose, the variety of sugar requiring least peptic change for absorption; and alcohol increases the absorption of sugar from the stomach (Schäfer).[7] The sugars generally seem more prejudicial than the starches. Probably this depends in part on their more facile absorption. All these observations are consistent with the view that gout depends upon hyperpyremia.

Consistent also are two seemingly opposed plans of dietetic treatment which have been advocated in gout. It is generally recommended to restrict very largely the intake of meat and other nitrogenous food-stuffs. Besides diminishing the intake of uric acid-forming material (an effect to be considered later), such would diminish the carbonization of the blood and thus tend to disperse hyperpyremia through an *impairment of function.* But Cantani and others have advised the restriction of sugars and starches, and prescribed a diet consisting largely of meat and green vegetables.[8] Such would involve, not an impairment of any function, but a marked diminution of the carbonaceous intake. Thus hyperpyremia would tend to disappear through a *diminution of supply.*

Exercise.—Foster says: "One hour's hard labor will increase five-fold the quantity of carbonic acid given off within the hour."[9] This is due not merely to increased exhalation of pre-formed carbonic acid from the blood, but to an increase in the rate of combustion whereby more carbonic acid is produced. Hence exercise promotes catabolic decarbonization, and is an efficient means of preventing or dispersing hyperpyremia. And it will be admitted by all that a physically active life is a preventive of gout. Gout "shuns the stout and healthy laborer . . . it seldom visits the active and athletic sportsman" (Gairdner).[10] But instances are recorded in which a fit of gout, impending or actually developed, has been aborted by exercise. Cullen, Gairdner,[11] and Duckworth[12] refer to cases in point.

On the other hand, gout "seizes the fat and dull farmer" (Gairdner).[13] Sydenham said: "The omission of any customary exercise brings it on," and "whenever I returned to my studies, gout returned to me."[14] Fothergill points out that indolence, whether voluntary or enforced, as by an accident, is an important factor in gout.[15]

Temperature.—Cold bathing is a powerful stimulant to combustion; and it seems probable that at least in some circumstances hot bathing tends to exert an opposite influence. If so, hot bathing would tend to precipitate hyperpyremia. Conformably Bannatyne has more than a suspicion that the acute arthritic outbreaks which so often follow spa treatment depend upon the "thermal action of the mineral waters when used externally."[16] He has seen them determined by plain hot water baths in those who were having no mineral treatment at all. Garrod has "seen a severe attack of gout brought on by taking a hot bath soon after dinner";[17] here the sudden diminution of expenditure would immediately succeed a sudden increase of income. And Henry Rayner, speaking of a stuporous lunatic with suppressed gout, says: "Hot air-baths were given . . . under their use, he soon developed severe acute attacks of gout."[18]

Diurnal Pyremic Fluctuations.—There is a regular fluctuation in the rate of combustion throughout the diurnal cycle. This may be gauged with probable accuracy by the temperature. At noon, and for some time thereafter, the temperature is at its maximum; during the small hours of the morning it sinks to its minimum (Jürgensen, Liebermeister.)[19] But the fluctuation in combustion is rendered certain by estimating the heat production. During the day from 216,960 to 140,000 calories, according as the subject is working or resting, are produced per hour; while during sleep the hourly production falls to 40,000 calories. (Lockhart Gillespie.)[20]

On the hyperpyremic theory, the time of onset of the acute gouty paroxysm—2 A. M., Sydenham; 1 to 4 A. M., Ewart—is readily explained. In ordinary circumstances, the carbonaceous income of the blood from the ailmentary canal is continuous though not of course uniform. Hence the tendency to hyperpyremia would depend in large degree inversely upon the rate of expenditure. Combustion is the most important form of expenditure, and therefore, hyperpyremia would most probably attain

its climax at such time as combustion sinks to its minimum.

Menstrual Pyremic Fluctuations.—It has been stated that the menstrual flow is one form of carbonaceous expenditure; and did space permit, a long series of facts* could be adduced to show that non-pregnant adult women depend upon this hemorrhagic decarbonization to avert a recurring menstrual tendency to hyperpyremia. Conformably Hippocrates said: "Mulier podagrâ non laborat nisi ipsi menstrua deficerint."[21] And Garrod admits "that it is not uncommon to find . . . the sudden stoppage of the catamenia immediately followed by a paroxysm."[22] Again, gout in women is most liable to arise shortly after the menopause (Garrod).[23]

Fat-formation.—A powerful anabolic capacity for fat-formation would be an important safeguard against hyperpyremia; and gout has been known to disappear from an erstwhile meager patient who as a result of change of air or other tonic influence has increased his capacity to construct fat and become obese. Savill records the case of a man who had suffered severely in past years from gout, but who became obese and thereupon ceased to suffer from arthritis.[24] It may be, of course, that the gout disappeared as a result of a change of diet, which change led to the obesity; but it is open for us to look upon the sequence of events as above suggested. Under this view rapid fat-formation and acute gout would both be acarbonizing processes (physiological and pathological respectively), capable of replacement, the one by the other.

Hemorrhage.—Hemorrhage other than that of menstruation would tend in the first place to disperse hyperpyremia; and Celsus pointed out that bleeding at the commencement of the attack caused some patients to remain free from gout for a year, some even for life.[25] Gairdner made a similar remark.[26]

Much evidence could be adduced to show that some persons (male not less than female) come to depend upon recurrent hemorrhage—epistaxis, hematemesis, hemoptysis, hemorrhoidal bleeding, hematuria, etc.—in order to meet a tendency to hyperpyremia. And Garrod says that the sudden suppression of an accustomed discharge of blood is often the immediate antecedent of a gouty paroxysm. Trousseau called attention to the danger—well recognized in his time—of interfering with habitual fluxes which he regarded as supplementary functions.[27]

Glycosuria.—We may suppose that in glycosuria the organism has acquired a new outlet for one form of carbonaceous material. On this view glycosuria would tend to antagonize hyperpyremia. It certainly tends to antagonize acute articular gout. Garrod saw several cases in which the supervention of glycosuria terminated gouty attacks which had been long recurrent.[28]

Plumbism.—Broadbent suggests that in this affection, the lead salts form compounds with organic matter, "albuminates of lead."[29] Such occurring in the active nitrogenous tissues, would in all probability damage the decarbonizing capacities, catabolic and anabolic, and so conduce to hyperpyremia. And the frequent occurrence of gout in plumbism is too well known to demand further evidence.

Paroxysmal Neuroses.—The inverse relations between acute gout and the paroxysmal neuroses have been recognized by a long series of physicians, including Henry Horland, Scudamore, Trousseau, Todd, and Livering.[30] Tissot referred to the relation of gout to migraine "as a matter of general observation."[31] Trousseau spoke of the two affections as "twin sisters," and referred to a case in which "attacks of asthma periodically alternated with attacks of articular gout."[32] Van Swieten related a case in which regular attacks of gout completely replaced recurrent epilepsy, which had followed recurrent gastralgia.[33] Garrod saw similar alterations, and quotes a remarkable case in point of Robert Wilson's. "A gentleman had suffered from epilepsy from the age of 20 to 52; the fits were frequent, sometimes occurring as often as once a week. He then had distinct articular gout in one great toe and afterwards experienced attacks of the same kind from time to time up to his death at the age of 72. From the first manifestations of decided gout, there was an entire cessation of the epileptic convulsions."[34]

As already stated, much evidence can be adduced to show that migraine, asthma, and major epilepsy own in some cases a common factor in hyperpyremia and constitute acarbonizing processes. On the hyperpyremic view of acute gout, but not so far as I can see on any other, all the inverse relations above enumerated can be explained. The four affections depend upon a common cause and exert a common effect. Their long-recognized affinity depends upon their common cause; it may be regarded as the affinity of blood relationship. But they are in a sense antagonistic, since, having a common effect, there is a certain improbability that more than one of them will be demanded in the one case; this antagonism may be regarded as one of mutual rivalry. There is a task open for competition and the successful competitor will be determined by the personal and environing factors of the individual. In other words, these diverse affections represent pathological capacities of different individuals.

Evidence that Acute Articular Gout is an Acarbonizing Process.—There is sufficient evidence to show that acute gout would be capable of dispersing hyperpyremia. It has been demonstrated experimentally that pyrexia depending on several different causes increases the rate of combustion and the output of carbonic acid (Liebermeister, Leyden, Fränkel.[35] Acute gout is a pyrexia lasting from two to ten days (Duckworth).[36] This suggests that acute gout increases the rate of combustion, and such has been demonstrated. "During the acute attacks, Magnus Levy has shown that the oxygen intake may be increased by 5 to 10 per cent." (I. Walker Hall.)[37]

Now the salutary influence of the acute gouty paroxysm has long been recognized. After such an attack there is often "a total or permanent cessation from those symptoms which are supposed to depend upon impurity of the blood" (Ewart).[38] In short, in the words of Laycock, gout is an excretory fever (Duckworth).[39] And further the patient can safely count thereafter upon a considerable period of immunity from arthritic attacks.

That the pyrexia is essential to the salutary action is shown in many ways. "The improvement which succeeds the attack is, as a rule, proportionate to the degree of febrile reaction" (Braun).[40] In acute asthenic or *subacute articular* gout there is "little heat or redness and all febrile disturbance may be absent" (Garrod).[41] This form, most common in women, is, Garrod avers, much more injurious than acute sthenic gout.[43] In *chronic articular* gout in which there is commonly neither redness, increased heat, nor pyrexia, the patient remains as a rule frankly cachetic; and Klemperer, Levy, and others have failed to demonstrate any material variation from the normal rate of combustion (I.

* These are set forth in the work already referred to.

Walker Hall).[43] Again, "it is . . . a well-known observation that gouty patients often remain for a long time free from paroxysms after a febrile malady of however foreign a nature" (Braun).[44] "In this way various acute febrile diseases and inflammations, like tonsillitis, bronchitis, rheumatism . . . afford great relief from the constitutional symptoms of arthritism" (Henry M. Lyman).[45] And finally it has been frequently pointed out that drugs, more especially colchicum, which cut short the arthritis and so the pyrexia, tend to prevent the amelioration in the general health which usually succeeds the uninterfered with acute attack, and to shorten the ensuing period of immunity from arthritic paroxysms (Trousseau,[46] Gairdner,[47] Fothergill,[48] and others).

Mechanism of Acute Articular Gout.—Garrod showed that "in true gout uric acid in the form of urate of soda is invariably present in the blood in abnormal quantities, both prior to, and at the period of, the seizure";[49] that at this time the elimination of uric acid as measured by the twenty-four hours excretion, is diminished;[50] "that the acid is thrown out in much larger quantities as the disease is passing off, and that then amounts even above the patient's daily average may be excreted, forming the so-called critical discharges; and that after a time the uric acid is again lessened, although not to the extent observed prior to, or at the commencement of, an attack.[51] Some more recent observers (Lecorché,[52] Futcher[53]) place the maximum excretion of uric acid earlier in the attack. These differences are of degree only, and may be neglected here. All it is necessary to admit is that uric acid is being retained in the blood prior to, and at the onset of, the attack, and is excreted in excess later.

We have seen reason to assume that in gout hyperpyremia is an essential factor, and that the paroxysm is an acarbonizing process. How, then, bearing in mind the facts demonstrated by Garrod, can we avoid the inference that the hyperpyremia is in some way responsible for the uric acid retention in the blood, and that the acarbonization permits of the free renal elimination of the uric acid. To me the inference seems almost irresistible, even though we remain long ignorant of the mechanism of such retention and releasement. Garrod sought to explain the retention of uric acid by assuming a temporary failure of excretory power on the part of the kidney. But this explanation seems inconsistent with the rapid recovery of free excretion which ensues under pyrexial conditions. We are now called upon to assume that the overloaded condition of the blood is of such a nature that the kidney is unable to exert fully its selective function upon it, in so far, that is to say, as concerns the contained uric acid. In short, we transfer the blame for the excretory failure from the kidneys to the blood.

Normal secretion or excretion depends upon at least two conditions: (1) a proper quality of the blood—supply; and (2) a proper capacity on the part of the organ concerned—function. In the event of an unexplained failure arising, it is as reasonable to blame the one as the other—the supply as the function. Our assumption then is not more audacious than that of Garrod, while it has this clear advantage, namely, that it explains, as no other assumption hitherto has explained, why and how the temporary renal disability comes to a natural termination.

The renal disability, depending on hyperpyremia, is terminated by acarbonization of the blood. Acarbonization depends upon the pyrexia; for when pyrexia is absent, as "in very chronic gout, the blood, even in the intervals between the exacerbations, was always discovered to be rich in uric acid" (Garrod).[54] The pyrexia depends upon the arthritis, for the intensity of the febrile reaction is proportionate to the degree of local pain (Braun),[55] and contrary to what obtains in rheumatism, to the number of joints affected (Charcot).[56] As regards the arthritis, we may continue to believe that it depends upon the sudden precipitation of biurate of soda in the sensitive articular structures. And the precipitation may be regarded, now as heretofore, as in the nature of an overflow from the sanguineous accumulation. I am aware that it has been stated that the blood is never saturated with uric acid in gout. That possibly applies to normal blood; but it by no means necessarily applies to the blood in hyperpyremic conditions. If hyperpyremia diminishes the excretability of uric acid, it is certainly not inconceivable that it may diminish also its solubility.

On the view adopted in this article, the steps in acute gout may be epitomized as follows:

1. Hyperpyremia from excess of carbonaceous income or deficiency of carbonaceous expenditure.
2. Progressive accumulation of uric acid in the blood—uricemia.
3. Deposition of a portion of the uric acid in a joint.
4. Acute arthritis.
5. Pyrexia involving increased combustion.
6. Acarbonization of the blood.
7. Free renal elimination of uric acid retained in the blood.
8. Recovery by the blood of its solvent power for uric acid.
9. Reabsorption of the extravascular articular deposits of uric acid.

Thus the acute gouty paroxysm may be regarded as a "pathological function"—as a conservative reinforcement of inadequate physiological function; and uric acid may be regarded as an essential instrument therein.

The weak point in this hypothesis as above stated is the unsupported assumption that hyperpyremia and its dispersion are responsible for uricemia and its dispersion respectively. But a considerable amount of quite independent evidence can, and later will, be brought forward to show that all conditions tending to cause hyperpyremia tend to cause uricemia, and that all conditions tending to promote acarbonization tend to cause free renal elimination of uric acid. Such evidence must be deferred, however.

REMOVAL OF THE LENS IN MYOPIA.

By JUSTIN L. BARNES, M.D.,
NEW YORK.

Ablatio lentis, or removal of the lens in high degrees of myopia, is now a well-established feature in ophthalmic surgery. This article will deal with a case of bilateral ablatio lentis and enter upon a somewhat detailed study of the subject in general.

Mary F., age 16, was first seen by me when 9 years of age. The degree of myopia present was very high, amounting, as nearly as I could estimate, to not less than 25.D. With the best correction I could find her vision and refraction were: R.V.= 5/200; 20/70—with—20.D.—1., cyl., axis 15°. L.V. =6/200; 20/70 with—22.D.—1., cyl., axis 165°. Owing to the excessive amount of myopia I advised her to withdraw from school, to avoid the use of her eyes at short range and to live out of doors as much as possible.

In October, 1903, I proposed to try and arrest the further progress of her myopia and also attempt to place her in a condition whereby she might hope to resume her education and fit herself for usefulness. Of the various operative methods for removal of the transparent lens, I chose, as I would not to-day after further experience and wider research, direct linear extraction. I first operated upon the right eye, as being the one having the poorer vision of the two. There were no serious fundus lesions contraindicating, marked posterior staphyloma and some choroiditis alone being present. With a keratome, under cocaine anesthesia, I made a linear section inferonasally (to counteract by cicatricial contrac tion her astigmatism) and lacerated the capsule, being very careful not to injure the posterior capsule. By gentle pressure I withdrew, so far as I could judge, the major part of the lens and by careful manipulation succeeded in not evacuating any vitreous humor. Then instilling atropine, I bandaged both eyes. Next day the anterior chamber was seen full of swollen soft lens matter. After a couple of weeks this had nearly absorbed, and a little later I needled the remaining membrane. Subsequently cyl., R.V.=20/30—W.—2.D.—1., cyl., axis 35°, a vision of two and one-third times what it was previous to the operation.

In February, 1904, I performed direct linear extraction upon the fellow eye, but with this difference in technique: I practised lavage with the Lippincott irrigator. After six days there was very marked reaction involving the eye in an iridocyclitis, even to the extent of a severe exudate and hypopyon. The eye appeared to be lost, the projection becoming almost entirely abolished. I was naturally greatly disappointed, but persevered in treating her vigorously with atropine, hot water compresses, inunctions and rest in bed. After the eye got well I sent the patient into the country with instructions to report in the fall. When she reappeared, I was astonished to find that the eyeball was sound, tension normal, iris-color restored, projection perfect, but a dense membrane to which the iris, with irregularly and laterally elongated circumference was attached, shutting out all sight except light perception. Moreover, there was a marked convergent strabismus, of which I will speak later. Having nothing to lose and much to gain, I determined upon an attempt to open this membrane. Under cocaine anesthesia I introduced a Gräfe knife up to the proximate pupillary margin and elevating the handle of the knife to a nearly vertical position, punctured the near periphery of the membrane. Then with the DeWecke scissors I made a longitudinal section of the membrane, when instantly the pupil became black and the pupil almost perfectly circular. After an uneventful recovery I found L.V.=20/30—W.—1.D., cyl., axis 180°, also a vision of two and one-third times that previous to the operation. At this writing, nearly a year after the last operation, her binocular vision remains 20/30.

Two points of great interest are to be considered. (1) She can read Jäger No. 1 at eight inches, with her nearly emmetropic correction and also without glasses. (2) The patient is still afflicted with convergent strabismus. Later in this article I shall discuss aphakic accommodation. The matter of her strabismus remains a subject of quandary to me. I found that she could at will fix with either eye and also that she could exhibit binocular vision. Instructing her to report monthly, she shows a gradual lessening of convergence. Now, previous to the operations this patient did not have divergent strabismus, so common in myopia. This indicates that she had some converging power, but on account of her high degree of myopia it could hardly have been associated with accommodation. If the eyes converged on account of the second eye having been amblyopic, by virtue of the presence of a dense membrane, then we might expect that the eyes would straighten when the second eye was placed on a par with its fellow, through the opening of the obstructing membrane as described, especially under the stimulus of the binocular vision present. This seems to be proven by the lessening of the convergence. It remains to be seen whether ultimately parallelism and binocular single vision will result. But the question ever presents itself: Why did convergent strabismus supervene? Is it perhaps to be explained by the new effort at accommodation (aphakic) which she plainly shows, operating as in all accommodative acts with the associated convergence in all eyes? If the convergence continues to lessen and binocular vision (diplopia) persists long enough, I am convinced that binocular single vision and parallelism will probably follow. At any rate, it is proper to wait and see what transpires before considering any further surgical interference.

History.—In looking over the history of this operation, it appears that it was probably first proposed by Desmonceaux, an abbe, who, in 1776, suggested the idea to Wenzel. The latter removed a

lens, but the result was unsatisfactory and nothing more of real value (although it is claimed that Beer did the operation in 1817) was heard of the matter until 1858, when Mooren of Düsseldorf, attempted the operation. Unfortunately it was likewise a failure. It was reserved for Fukala, whose brilliant work, begun in 1889, brought the matter into prominence. There has been some controversy as to Fukala's claim to be the practical originator of the operation, but I agree with Fukala who himself says: "That he is the true founder who brings about this result through really and successfully acting through a recognition of the laws of optics." There is no question that the operation has been previously performed, sometimes for the correction of myopia and also that myopia has been corrected incidentally through cataract extraction. But for the neutralization of myopia, *per se*, and with success and for bringing the operation into perfection of detail, we must give Fukala the chief credit. Oswald in 1891, Operon in 1895, Hirschberg in 1897, and many others have followed in Fukala's footsteps, until today the operation is widely performed, especially in Europe.

Rationale.—As is well understood, the raison d'être for ablatio lentis lies in the fact that the need of the great strength of the myopic concave correcting lens is immensely reduced by the removal of the convex crystalline lens. This reduction amounts to a sum total of from fourteen to about twenty-two dioptres, some authors claiming even more. If, by the removal of this high degree of refractive error, the vision is greatly improved, the necessity for wearing heavy and powerful lenses avoided, and the patient better fitted for his occupation, it cannot be denied that the rationale of this procedure is evident. To this operation may be attributed the fact that there are now a large number of persons successfully engaged in various pursuits who were more or less helpless and dependent, thus materially relieving society of the burden of their support and adding to their personal welfare and comfort.

Selection.—According to Vacher,[60] "Progressive myopia beginning at the age of twelve, should be operated if the myopic dioptres surpass the number of years of the patient."

In the selection of cases suitable for ablatio lentis the age of the patient and the degree of the myopia play the important rôle. Within reasonable limits, provided the myopia be of sufficient degree, the younger the patient the more favorable the case, although the lens may be removed at any age. Ordinarily we would not think of removing the lens of a patient under the age of ten years, nor would we care to undertake the operation on a patient over fifty years old. It is commonly conceded that the degree of myopia must be about 14 or 15 dioptres or more. Other considerations influencing the selection of operative cases are such as when vision is not improved by glasses; when there are no serious fundus lesions; when the vision is very low even with the best glasses, and where there is divergence and no longer binocular single vision. We naturally hesitate when a patient has but one eye, but even here, if the vision is low, the conditions otherwise favorable, and glasses do not give satisfactory vision, it would seem indicated.

Reported Cases.—Up to this writing, there have been about 2500 of these operations reported from abroad, while, after a painstaking search of the literature of this subject, I have found not quite fifty cases reported in America. It is very possible that there are more, but I have not been able to find them. While this very great disparity in the number of cases as reported from Europe and America may be partly explained by the fact that myopia, especially of high degree, is far more prevalent abroad than here, it is nevertheless a disappointing revelation that so little has been done in this field in this country. It is true that foreign surgeons undoubtedly have an almost decisive influence and control over their patients, for very well-known reasons, while in America the reverse is very much the case. Nevertheless, it is to be hoped that, with time and experience, the greater number of more or less hopelessly handicapped myopes will discover the benefits of this operation.

Methods.—There are several methods to be considered in removal of the lens in high degrees of myopia. (1) Direct linear extraction in the young. (2) Direct extraction after the usual cataract methods in patients over fifty. (3) Repeated discissions. (4) Discission with linear extraction (Fukala).

(1) Direct linear extraction has been done a relatively small number of times and does not meet with approval. This is due to the fact that it is difficult to know when all or the greater part of the lens has been removed and is accompanied by the danger of loss of vitreous. If the latter presents during the operation it may not be differentiated from lens matter, and lens matter which it is our aim to evacuate may be left behind. In such cases the reaction may be very severe and the loss of vitreous may be followed by detachment of the retina.

(2) When we have reason, on account of age of the patient, to suppose that the lens is more or less hardened, with at least sclerosed nucleus, the removal of the lens by discission is contraindicated and we resort to extraction after the same methods as in ordinary senile cataract. The operation is rarely performed at the age at which this method would be indicated; nevertheless, it has been successfully done at the age of sixty-five.[101] Fukala states that myopic lenses can be removed by discission up to the age of sixty years, and while in certain senile cases this might be done, in other cases it would seem better to remove the lens through the methods adapted to ordinary cataract extraction. He claims that the myopic lens hardens very much less rapidly and thoroughly than others.

(3) Some operators, especially in America, prefer to remove the lens by cautiously repeated discissions. This method may perhaps have the advantage of a certain degree of safety, but it is open to the serious objection of consuming a long time and in discouraging the patient. I do not believe that it is a justifiable method as there is always the added danger of infection, which necessarily must be considered in common with each and every entry of the globe. Its claimed advantage of preventing detachment of the retina is, to my mind, a practicably negligible quantity. Moreover, even after careful discission, the lens matter may undergo swelling to such an extent as to necessitate immediate linear extraction.

(4) Fukala's operation, namely, free discission with linear extraction is, in the light of wide experience, the now well-established method of ablatio lentis. This operation, as I have said, bears Fukala's[78] name and justly, because this operator was (in 1889) the first to work it out, develop it, and exploit it with success in a very large number of cases. Fukala has been through several stages in his work, operating at first with cautious discissions and later making very free discissions even with a Gräfe knife, and varying the procedure with iridectomy, which later (1894) he abandoned. Though he changed his views regarding the advisability of iri-

dectomy, he does not, I think, hesitate to excise a portion of the iris in cases advanced in years. Froelich[76] thinks there is danger of glaucoma in using the knife, and prefers repeated discissions. It is, after all, a matter of personal judgment and experience. Rogman[53] states that posterior discission is dangerous and Rohmer[54] first produces artificial maturation, followed by linear extraction in the adult and suction in children.

There results, as after cataract extraction, the remaining interference with vision due to the presence of a more or less opaque capsulary membrane which is dealt with as in any post-operative lenticular membrane. As the pupillary margin of the iris is more or less regularly and firmly bound to this membrane, I am inclined to think that the best results are obtained by its division through the combined use of a Gräfe knife or keratome (for corneal incision) and the De Wecke scissors, though sometimes the membrane may be incised with a Gräfe knife alone. A preliminary iridectomy may be done, particularly in aged patients. Jocq (Paris) proposes injection of aqueous with a Pravaz syringe, but it is difficult and not recommended.

The incision should be so placed as to tend to correct any existing corneal astigmatism, and, in judging of this, *only* corneal astigmatism should be considered, inasmuch as lenticular irregularities will necessarily be abolished. Except where strongly contraindicated the bilateral operation should be performed.

The preparations for operation should be, as in all operative work, conducted under strictly antiseptic precautions. The after-management of these cases differs in no way from that following any operation involving opening of the globe. Whether one chooses to employ the open wound method, which is has been more recently exploited, or the closed method which is more common, is a matter of the personal equation. Each has its advantages and disadvantages. It is hard to say whether an eye is more or less exposed to infection by either method, but on the other hand the eye is perhaps more guarded from the dangers of accident if the eye is bandaged. There is, of course (with the exception of the extraction of senile lenses where a flap has been made), very little danger of subjective mechanical interference with the wound (for the latter is very small in the usual Fukala operation) if the eye should be treated by the open method, but I would advise that at least a mask be worn for general protection. This may have one or two small perforations for admission of air. However, I am personally inclined to practise the closed method and treat a myopic ablatio lentis after the manner usual in ordinary discission and extraction. After a free discission, however performed, the eye must be closely watched, often inspected, kept carefully sterile and upon the appearance of severe reaction and particularly in the advent of increased tension the lens promptly extracted by the linear method. As this entire operation is a pronounced traumatism atropine and ice may be freely and continuously used, especially after the anterior chamber has been reformed, following the extraction. Panas[47] says atropine is contraindicated and that increase of tension should be avoided with eserine. If an iridectomy has been performed, and the pillars carefully replaced, there will be little danger of a synechia, but if no iridectomy has been done we may have this misfortune. It is probably wise to exclude bright light from the patient's eyes. This is best done, not by darkening the room, but by means of a mask or drop shade. The patient should have all the benefits of fresh air, he should be in bed as long as indicated, and the diet and other general conditions regulated.

The *Contraindications* in extractio lentis are: (1) A known hemorrhagic tendency. (2) Choroidal degeneration and lesions in the mascular region. (3) Loss of one eye. (4) Advanced age. (5) Ability to see well with the myopic correction.

(1) The hemorrhagic tendency is quite rare, more or less obscure and uncertain. It is doubtful whether all other conditions being favorable, this condition should debar a very much crippled patient from the benefit of this operation, at least on one eye. In such a case the second eye might be operated upon subsequently, if success with the first eye warranted it.

(2) Extensive choroidal degeneration is, by general though not unanimous consent, considered a bar to this operation. Pflüger[100] says that fundus lesions, choroiditis especially, are indications for removal of the lens in high myopia. Abadie, Vacher[60], and Panas[50] agree with Pflüger. The majority of operators (Fuchs[77], Coppez, Pergens[99] et al.) believe that choroidal atrophic lesions accompanied by macular involvement constitute a contraindication. Bruns[34] says that young subjects without, and old with, fundis lesions should not be operated upon.

(3) Of course, as I have intimated, we should hesitate to operate upon a patient with only one eye, for fear of a result of total blindness, which, naturally, would be worse than the poorest possible previous vision.

(4) The removal of the lens in advanced years is thought to be more serious than in youth, and besides, there is the added jeopardy accompanying all operations in late life, although Rogman[115] operated successfully on a man of sixty-five years. It is obvious that there is no justification in subjecting to even the smallest risks the eyes of a patient who sees well with glasses.

The *Advantages* of removal of the lens are threefold: (1) Visual; (2) Muscular; (3) Antipathological.

(1) Vision is commonly improved from one to five times or more. Fukala[83] says that the improvement of sight is due not alone to increase of the size of the retinal images, but also to the increased illumination and to the fact that there are no longer any lenticular reflexes.

(2) A previous divergent strabismus with monocular vision is often converted into a binocular single vision. On the other hand the cramp of excessive accommodation brought about by certain occupations, is no longer possible, and coincidentally the accompanying convergence is relieved.

(3) The opinion is largely held by most operators, that the abolition of dynamic vision by its very resulting passivity arrests the progress of myopia, while on the other hand certain fundus lesions, particularly if not involving the macular region, are also arrested.

The *Dangers* that may be encountered in ablatio lentis are: (1) Hemorrhage and loss of vitreous humor; (2) Detachment of the retina; (3) Incarceration of the iris or capsule; (4) Glaucoma; (5) Iritis; (6) Infection.

(1) The liability of Hemorrhage and Loss of Vitreous appears to be very slight, and happening chiefly if there be some macular lesion (Schroeder), or faulty technique, which occurs probably no more frequently than in any operation upon the lens, not including discission.

(2) Detachment of the retina, according to European authorities, occurs in only three to five per cent. of cases. It might occur without the operation and fear of it need not bar (Speyer).

(3) Incarceration of the iris, or of the capsule, depends very largely upon the site of the incision, the toilet of the wound, and the management of the case afterwards.

(4) Glaucoma can be avoided by extraction within a proper interval after the operation, and it should not occur in a carefully watched case. Even if it does supervene, prompt extraction naturally reduces the tension before serious injury is sustained.

(5) Iritis does undoubtedly occur in certain instances. It appears often enough in any surgical procedure involving section of the anterior portion of the globe, but its possible advent does not in this day operate as a contraindication in cataract extraction, and can be dealt with in the myopia operation, with confidence and satisfaction.

(6) Of the dangers of infection, I need say no more than that in these days of antisepsis, it is nearly inexcusable if, upon opening the dressings, the wound is found to be infected. The difficulty of excluding possible infection through the tear passages, should constitute practically the only source of infection, and even this is excluded by many surgeons, by ligature, etc.

Justifications.—The operation of removal of the lens in high degrees of myopia is justifiable: (1) When vision cannot be improved by glasses; (2) When there are no serious fundus lesions; (3) When the myopia amounts to 15 D. or more; (4) When there is evidence that the degree of myopia, already high, is rapidly increasing.

(1) It seems reasonable to conclude that when a patient has a high degree of myopia with correspondingly low vision and when repeated trials have shown that his sight cannot be improved with glasses, he would be a suitable subject, other things being equal, for any procedure promising material improvement. This has been repeatedly demonstrated through this operation.

(2) Regarding the matter of lesions of the fundus, there is no contraindication to be found in choroiditis, for example, or in many other lesions, provided there be no involvement of the macular region; indeed, I repeat, it is strongly claimed that extractio lentis generally arrests the very disturbances which would seem to make one hesitate to operate.

(3) Experience has proven that we should aim to neutralize the existing myopia; therefore we naturally infer that there is no indication for removing the lens when by so doing we might produce any considerable amount of hypermetropia, while we have yet to see a case in which any injury *per se* has followed the removal of the lens in cases of myopia of the highest known degrees.

(4) When there are unquestionable evidences of rapid progress of myopia anything that can be done to arrest it will certainly be justifiable. Happily, it is the almost common consensus that ablatio lentis, does actually arrest the progress of myopia, supposed to be accomplished through inhibition of accommodation and the attendant relaxation of convergence, factors prominent in the development of myopia.

The *Optical and Physical Effects* of this operation are: (1) Alteration of refraction; (2) Loss of accommodation; (3) Improvement in vision; (4) Changes in muscular action; (5) The prevention of the increase of myopia; (6) The arrest of the progress of choroidial lesions.

(1) The alteration in refraction consists in a reduction of the myopia of from 14 to about 22 D. (2) Although lenticular accommodation is lost, there is developed in many myopic patients, an aphakial accommodation of which I have treated elsewhere in this article. (3) The improvement in vision is an increase of visual acuity of from 1 to 4 times that previously existing, as stated above, and sometimes the increase is much more than this. (4) The changes in muscular action consist of a stimulation to convergence, tending toward binocular single vision, and also toward a less dynamic visual act, thus leading to inertia, thereby (5) arresting, as mentioned, the further progress of myopia physiologically and (6) pathologically. This is denied by Panas, Fuchs, Coppez and Pergens.

The Results of successful removal of the lens in myopia may be considered under the heads: I.—Immediate effects; II.—Remote effects.

I.—The Immediate Effects are: (1) Pronounced reduction of the degree of the myopia, the cardinal feature and prime consideration in the operation; (2) Marked improvement in distant vision; (3) Distinstness of vision is markedly increased; (4) Accommodation is abolished; (5) Convergence is relieved; (6) Enlargement of retinal images.

II.—Among the Remote Effects are: (1) Continued improvement in vision; (2) Cultivation of the so-called aphakial accommodation; (3) Restoration of binocular single vision; (4) General passivity of the visual act which is no longer dynamic.

I.—(1) As we have already said, the change in refraction amounts to a reduction in the myopia of an amount equal to 14 to 25 D. (2) The vision is improved some four or five times, and therefore (3) the distinctness is immensely accentuated. (4) The abolition of accommodation is not a serious loss, for the twofold reason that (*a*) its presence was a contributing factor in the development of myopia and (*b*) a patient with high myopia loses eventually the advantages of accommodation since his punctum remotum is within the field in which accommodation is commonly improved. (5) Convergence is relieved by virtue or removal of the punctum remotum to that approaching emmetropia. (6) To the enlargement of the retinal image is due in no small measure the increase of vision.[83]

II.—(1) As time passes we note with satisfaction an improvement steadily increasing in the amount of visual acuity. This is commonly observed in cataract operations. (2) In the matter of aphakial accommodation Loring thought that the accommodation (which does certainly exist) might be attributed to the subject's ability to interpret with increasing accuracy retinal circles of dispersion, while Förster,[75] who was the first to note aphakial accommodation, thought it might be due to changes in the curvature of the cornea. Woinow[112] performed interesting experiments in which he satisfied himself that certain changes in the curvature of the anterior surface of the vitreous humor were produced by the action of the ciliary muscle. The question is not really a settled one. Is it an optical or a mental process? It may be both. (3) As we all know, many myopes have divergent strabismus. Under the stimulus of improved vision and perhaps also on account of the aphakial accommodation there results sometimes binocular single vision after a preliminary period of diplopia. In the case heading this paper I have seen a marked convergence of the visual axes with diplopia as an immediate result of the operation (bilateral), and I am watching the gradual development of parallelism. (4) Owing to the destruction of the dynamic force of accommodation and the relief from the previously necessary (except where the eyes abandoned all attempts at binocular vision) convergence, there results as I have mentioned, a general quietude of the eye quite conducive to the checking of progressive myopia.

Erythropsie is sometimes noticed for several weeks, as in post-operative cataract subjects.

As is well known, Donders and Von Graefe were steadfastly opposed to this operation and regarded the removal of the transparent lens as malpractise and without a vestige of excuse. Von Graefe considers that insufficiency of the interni plays an important part in the progress of myopia and believes in the beneficial results of tenotomy of the externi. Emmert[72] regards the operation with disfavor. Otto,[97 98] Vossius[109] and Von Hippel,[91] do not approve because of fear of detachment of the retina, while Gelpke[85] says that occurring after several weeks, a detachment cannot be attributed to the operation, and LeGrange[43] believes the operation lessens this danger. Stood[108] declares that there is no danger in operating upon eyes having 12 D. or more, does not think the operation adds to the danger of detachment and adds that even after five years of observation the refraction continues to change. Scheffels[105] says that one-fifth of his cases remained stationary in refraction after four years, while the remainder became less hypermetropic, indicating that myopia still increases somewhat after operation; he suggests that the mal-influences producing myopia may persist for a while. Fuchs,[77] who is a safe and conservative observer, thinks that the operation does not prevent the usual progressive myopic changes and believes that the operation, while useful, must be restricted in application. Parinaud does not believe that the operation will arrest myopia. Distler[71] is a powerful advocate of the Fukala operation. He asserts that it is dangerless, believes that binocular single vision is likely to be restored and insists that the further progress of myopia is stayed, while danger of hemorrhage and detachment is neither increased nor lessened. Genistous[39] believes in operating even in fundus lesions. I do not believe that fear of detachment should militate against the operation; nor do I consider, even if it should be shown that myopia does increase after ablatio lentis, that this should constitute a contraindication, for it is still more likely to increase without interference.

General Consensus.—There is a wide diversity of opinion as to the advisability of ablatio lentis in myopia. In searching through the literature of the subject, I have found this to be the case from such men as Emmert[72] (with fifty operations), who condemns it, to the conservative men who do it in carefully selected cases (Fuchs[77]), to its most brilliant and prominent advocate, Fukala, who has successfully performed it in a very large number of cases. It, however, appears that the large majority, particularly of European ophthalmologists, believe that the Fukala operation, in spite of its not being ideal in all respects, is, within certain limitations, indicated, and that it constitutes a very great advance in eye-surgery. It is generally believed, as I have said, that myopia and many of its attendant pathological lesions, are by such operations arrested, and subjects restored to independence. In the United States so few operations of this character have been done that American statistics do not afford a basis for any conclusive opinion.

RECTAL INJECTIONS OF LARGE DOSES OF SODIUM SALICYLATE IN CEREBROSPINAL MENINGITIS.

By A. SEIBERT, M.D.,
NEW YORK.
PROFESSOR OF PEDIATRICS, NEW YORK POLYCLINIC; ATTENDING PHYSICIAN, ST. FRANCIS HOSPITAL.

In view of the gloomy reports on the treatment of cerebrospinal meningitis coming from near and far (the *Deutsche medizinische Wochenschrift* of May 11, 1905, reports a 50 per cent. mortality among 1,955 cases in the province of Silesia, Germany, during the last four months), I hope to be pardoned for calling attention to a plan of treatment which has appeared effective to me during the last four years, although my experience is but a limited one.

Case I.—Young woman, 20 years of age, living in Newark, N. J. She began with severe continuous headache, nausea, and drowsiness on the first day, followed by high fever (103°—106.2°F.) hyperesthesia, opisthotonos, Kernig's sign, herpes, and extreme dilatation of the pupils during the second and third days of illness. Recognizing the severity and the bad prognosis of the attack, on the third day, I concluded to give *large* doses of sodium salicylate, with the object of possibly interfering with the vitality of the diplococcus intracellularis. As vomiting was still present on the third day (when seen by me first), I ordered fifteen grains, dissolved in a tablespoonful of warm water, to be injected into the rectum every hour until ten doses had been given, and two hours later one dose of fifteen grains of antipyrin, to relieve the violent headache. During the next twelve hours all medication was stopped, to begin again in the same manner after this interval. Headache, temperature, and pulse were markedly improved on the next day; opisthotonos, hyperesthesia and nausea disappeared during the second and third days of treatment, but Kernig's sign, dilatation of the pupils and muscular tremor were still present during the two weeks after the temperature reached the normal, five days after the beginning of treatment. From the third day of treatment but six doses of the salicylate were given daily; and from the seventh on but three. Antipyrin was used but once. This case was observed in May, 1901.

The following cases were seen during the present epidemic:

Case II.—George Lindley, aged 22 months, seen first on Feb. 23, 1905, in consultation with Dr. Elsing in Richfield Park, N. J. Illness began five days previous with sudden vomiting, fever, and marked restlessness. Status: Marked opisthotonos, Kernig's sign, enormous herpes over entire chin, both lips and tongue, temperature 103.5° F., persistent vomiting, about twenty large pale roseola. Orders: A large watery enema every twenty-four hours, then fifteen grains of sodium salicylate per rectum every six hours. (Six thousand units of diphtheria antitoxin were also injected during the first three days of treatment, to test its efficiency.) The first dose of the salicylate was given on Thursday at 8 P. M., and on the following Sunday morning the fever, the opisthotonos, hyperesthesia and nausea had disappeared, after 150 grains of the drug had been given in 60 hours in fifteen-grain doses. When seen again on the following Tuesday the Kernig, the herpes and the dilated pupils were the only symptoms of meningitis left. Child was sitting dressed on mother's lap, was hungry, and enjoyed good sleep at night. Two doses of the salicylate were given daily during the next three weeks. Uneventful recovery. The extended experience of others has since proved that the speedy recovery in this case was not due to the diphtheria antitoxin.

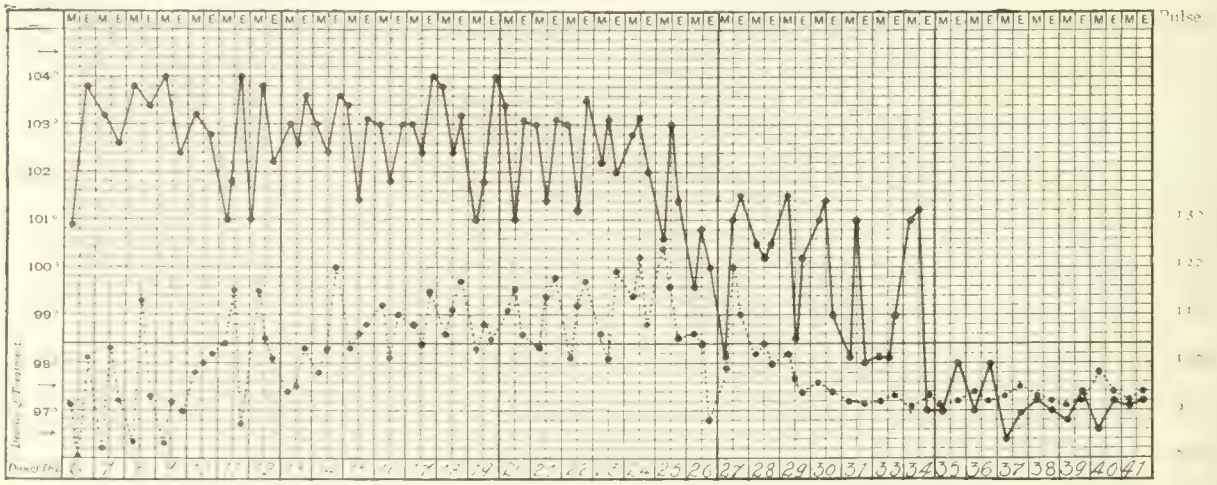

Chart I. The salicylate treatment was begun on the 25th day of the disease.

Case III.—Anna Reimer, aged 10 years, was first seen by me in consultation on March 27, 1905, three weeks after the beginning of her illness. Status: Marked emaciation, opisthotonos mild, muscular rigidity of back, Kernig and hyperesthesia very marked, nausea, anorexia, temp. 103.2° F., pulse 120, slow answers, stupor, pupils dilated ad maximum. On Chart I. the temperature and pulse (taken by a trained nurse) before and after the salicylate treatment can be seen. On April 5th I was given charge of the case.

Treatment: A large watery enema every twelve hours, fifteen grain doses of sodium salicylate per

rectum every six hours, fluid diet every three hours during daytime (with hydrochloric acid before each meal), plain cold water at night. The drug action on pulse and temperature are best seen on the chart. Muscular rigidity, nausea, headache, and hyperesthesia disappeared gradually within four days, but Kernig's sign, dilated pupils, and muscular tremor could be demonstrated fully four weeks after temperature and pulse had become normal. During the first week of treatment (the fifth of illness) 420 grains of the salicylate were given, in fifteen-grain doses every six hours. No heart depression was noticed, although no stimulants of any kind were used. The salicylization of this patient was gradually diminished to two fifteen-grain doses per diem, which, however, were continued for four weeks. The gain in weight and strength in this case was quite as marked as in the others.

Case IV.—Emilia Becker, female, aged 4¾ years. Sudden illness on May 9 with persistent vomiting and fever. Status: Tonsils reddened, no exudate, adjoining lymphnodes enlarged, temperature 102° F. Treatment: Iodine carbolic solution every hour and aspirin five grains twice daily. May 10: Nausea continues, large pupils, occasional strabismus. May 11: Marked strabismus, opisthotonos, herpes, Kernig, nausea.

Treatment: Sodium salicylate, fifteen grains every *six* hours per rectum. May 12: Same dose every *three* hours per rectum, on account of persisting symptoms. May 13: Much better (best seen on Chart II), retains food, medication as before. May

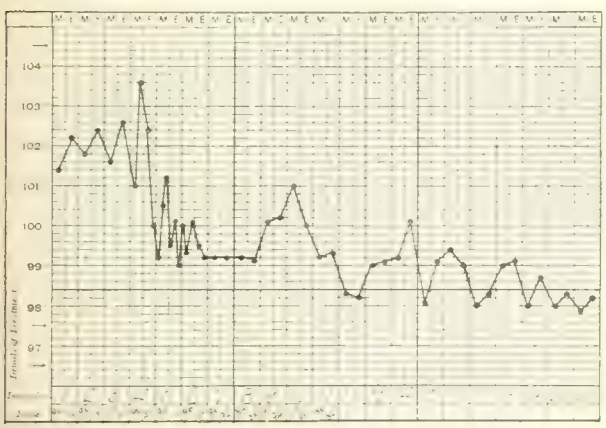

Chart II.

14, 15, 16: Daily improvement. Opisthotonos, strabismus and anorexia have disappeared. Demands to be dressed, eats and sleeps well. Complains only of hunger. One short rise of temperature to 101° F. and three to 100° are noted, otherwise temperature remains below 100°. Able to stand, walk, and bend forward seven days after beginning of treatment. Salicylization gradually diminished in frequency, but kept up for three weeks. From May 4 to May 22 the patient received 555 grains of salicylic soda in fifteen-grain doses, and from May 11 to May 20 750 grains.

Case V.—Antonio Macetti, age 4½ years, was brought to my clinic on Sept. 15, 1904. History: Had cerebrospinal meningitis during April and May of 1904, the fever lasting seven weeks. Status: Well nourished boy, abundant adipose tissue. Muscles flabby. Marked strabismus convergens. Left-sided spastic hemeplegia, most marked in upper extremity. Occasional opisthotonos. Posterior cervical muscles contracted. Cannot keep head upright; cannot sit alone. Complete aphasia. Deaf. Kernig marked. Toes pointed, more in left than right foot. Ravenous eater. In presenting this case to my students a serous exudate was assumed to cause many of the pathological phenomena by simple pressure. If this pressure could be removed, some of the symptoms would disappear, but such as were caused by destruction of nerve tissue would remain.

Treatment: Without the slightest expectation of a good result fifteen-grain doses of sodium salicylate were ordered four times daily, per rectum. An enema every morning. Diet regulated. Patient seen weekly. Improvement noticed after first week. Same treatment continued from week to week. In two months the boy was able to sit up, hold his head straight, to walk and to say "Mamma" and "Papa." The spastic hemiplegia had been so far improved but the left arm and hand appeared yet somewhat awkward in attempting to grasp a finger, but by Christmas this had also disappeared. The same treatment has been continued since. When presenting this patient, on May 26 of this year, to my students (one year after his acute attack), we found him normal in every respect, but for complete deafness and a limitation of speech to the words "Mamma" and "Papa." Considering the result of this late treatment, what could have possibly been achieved in this case by a constant and efficient flooding of the blood of this child with salicylates during the first days of his cerebrospinal meningitis in April, 1904?

Remarks. During the last four years I have seen in all but nine other cases of cerebrospinal meningitis in consultation, all of them more or less moribund, and therefore not worth counting. In one tubercular case, which Dr. Spalding was kind enough to show me, we became convinced after a fair trial that salicylate of soda was not effective in tubercular meningitis, as we both had expected. Three lingering mild cases of the cerebrospinal variety seen in my service in St. Francis Hospital all recovered promptly on salicylate of soda. In not one of the detailed cases reported here was Quinke's tapping of the spinal cord resorted to, because the clinical picture in each case was sufficient to establish the diagnosis, and as I did not wish the therapeutic result to be attributed to the tapping. Tapping may be of great value in some cases of meningitis, may save a life occasionally by relieving pressure, but is no more *curative* in meningitis than the tapping of the pleura in rheumatic pleurisy. Injections of antibacterial fluids into the spinal canal will never reach the organisms they are intended to destroy. An effective remedy for cerebrospinal meningitis will have to travel the same road which the infectious germ has taken—through the blood current. Salicylates have been used for some time in cerebrospinal meningitis, but to my mind the doses used heretofore have been *too small* entirely. If nothing more has been proved by this report (which, on account of its few cases I would be almost ashamed to present if it were not for the high mortality reported), it is the fact that *large* doses of salicylate of soda can be given per rectum to cerebrospinal meningitis patients without harm. The value of rectal medication in meningitis is evident. Rectal administration of sodium salicylate solution was first recommended by the author in 1889 (*N. Y. Medicinische Monatsschrift*) and again in 1891 (Medical Record, September 12, 1891), and has been used since. Only per rectum can *large* doses be introduced into the system without causing gastric disturbances. The introduction of this drug by venous injection as recommended by Mendel (*Therap. Mon.*, 1904) in articular rheumatism might be worth a trial in severe onsets of cerebrospinal meningitis.

In closing this report I hope that men in charge

of a large number of cases of this disease in their hospital service will give this plan of treatment a fair trial. In view of the great mortality any rational device appears worth trying. Personally I am convinced that this treatment is of value in all cases where serous, not purulent, exudate forms.

Effective sodium salicylate solutions must retain the color of distilled water. Yellow discoloration proves chemical changes, rendering the drug inefficient. When the rectal mucosa becomes irritated, a further dilution of the drug is indicated. Lateral compression of the sphincter ani assists in retaining the solution in the bowel. Small doses, given at shorter intervals, are ineffective.

114 East Fifty-seventh Street.

THE MEDICAL PHASES OF THE IMMIGRATION LEGISLATION.*

By VICTOR G. HEISER, M.D.

[illegible] CHIEF QUARANTINE [illegible]

My response to your kind invitation to read a paper upon the subject of immigration was prompted by a profound sense of the honor conferred upon me, but as I began to realize the full responsibility of the step, my difficulties in presenting the subject in an intelligent manner have given me many anxious moments. However, in taking up your time with the subject of immigration, I offer no apology, because I feel that the question is of the greatest interest to us all, not only as medical men, but also that we may intelligently discharge our duties as citizens.

It is my intention to discuss the subject of immigration briefly from its medical standpoint only, but a brief résumé of the legislation upon this subject may not be amiss.

The immigrant has been viewed with suspicion since the birth of the nation. In John Adams' administration we had the Alien act. The Hartford Convention, 1812, proclaimed "The stock population of these States is amply sufficient to render this nation in due time sufficiently great and powerful." In the discussion of the bill before Congress to provide a territorial form of government for Kansas and Nebraska, Senator Clayton of Delaware introduced an amendment to confine the elective franchise to native Americans, but this amendment was lost. The first legislation pertaining directly to immigrants was passed March 2, 1819. A clause in this act provided for their enumeration, also the registration of the age, sex, and place of birth. It was hoped to regulate by this law the transportation of immigrants, to prevent overcrowding on ships, and to provide for the correction of abuses on vessels.

In the debate on the bill, approved May 29, 1830, dealing with the preemption rights of settlers on public lands, Senator Merrick of Maryland offered an amendment barring aliens from participation in such privileges, but the amendment failed. In the fifties, the "Know Nothing" movement attained a large following. Its adherents not only recommended discrimination against aliens, but persecution as well. Some years after this, however, the development of the United States proceeded so rapidly with the assistance of the alien that almost all opposition died away. Laws for the regulation of immigration have always been the result of popular demand, and they have been passed with the view not so much of lessening the total number of immigrants as of preventing the admission of certain undesirable classes.

For many years, then, the subject of immigration has been a question which received much attention from the people of the United States, but it was not until 1875 that the views of the majority crystallized into any real legislation. Since that time, however, acts of Congress relating to immigration have followed one another in rapid succession. Each law added to the restrictions to be imposed upon arriving aliens, until the list of causes for exclusion has become a very long one. It is quite natural that a country like the United States, whose future in a large measure depends upon the class of people who are to be granted the privileges of citizenship, should wish to admit only those who are the most desirable.

It was not until the Act of 1882 that any cognizance was taken of the physical condition of the immigrants. In this law, it was provided that "any lunatic, idiot, or any person unable to take care of himself or herself, without becoming a public charge . . . shall not be permitted to land." It will be seen that the exclusion was only conditional, and since there was not much risk involved for the friend of the afflicted one to state that he would take care of such person, the object of the law was defeated in the great majority of instances. Another unsatisfactory feature was the fact that although the law was a national one, it was administered by State officials upon the authority contained in special contracts with the Secretary of the Treasury. Thus, it was quite possible that an immigrant refused admission at New York, for instance, might gain admission elsewhere. The next act was passed in 1885, and is generally known as the Contract Labor Law. This law contained no medical features. In 1888 came the Chinese Exclusion Law.

The act of 1891 was a more radical step than any that had heretofore been attempted. It was the first time that persons suffering with certain mental or physical conditions were absolutely excluded, and the law provided for the first time for the medical examination of all arriving aliens. This latter examination was to be made by the officers of the Marine Hospital Service. The law provided that "all idiots, insane persons, paupers, or persons likely to become a public charge, persons suffering from a loathsome or a dangerous contagious disease . . . shall be excluded from admission into the United States."

It will therefore be seen that the medical features of the immigrant legislation consists of two simple divisions. The first, for those suffering from afflictions for which they are absolutely excludable; and second, for those suffering from afflictions which may cause them to be likely to become a public charge. The phraseology of the law has been found in practice to be very fortunate. Whenever a certain disease, owing to its contagious character, becomes a menace to the public health, it can be placed upon the excluded list, or if persons suffering with certain afflictions are found to become public charges, the matter can be regulated by administrative action and thus the tedious delays incident to legislation avoided.

The constant aim of those having the medical inspection in charge has been to build upon practical rather than theoretical grounds. From year to year, as experience increases, it has been found desirable to augment the list of diseases that come under both divisions of the law. The last act of Congress pertaining to immigration was passed in 1903. From a medical standpoint that law still further increased the list of absolutely excludable diseases. The clause containing the addition specifically states that "insane persons, epileptics, and persons who have been insane within five years, or persons who have had two or more attacks of insanity at any time previously . . .

* Read at the first scientific session at the second annual meeting of the Philippine Islands Medical Association, held March 2, 1905.

shall be excluded from admission into the United States."

It will perhaps be interesting to discuss more in detail those diseases which are on the absolutely excludable list, and more particularly those which give rise to the greatest number of rejections.

The disease which easily ranks first in this respect is trachoma. The remark is often heard, "Why should this minor disease, a mere inflammation of the eyelid, be the cause of so much concern?" Trachoma was made an excludable disease in 1897. The medical profession, and more particularly the physicians in charge of the eye clinics in large cities strongly urged this step. They pointed out that their clinics were overrun with trachoma cases. Treatment pursued month in and month out was practically of no avail. Persons suffering from other eye diseases who really could be helped were crowded out. The contagious character of the disease constantly led to the infection of others. A case of trachoma introduced into a crowded tenement often caused the disease to spread throughout a whole block like wildfire. The cost of treating trachoma was becoming a heavy item of expense to the community. Further investigation showed that 15 per cent. of the inmates of the public blind institutions of the United States had become blind as a result of trachoma. Since the number was constantly increasing, it became quite clear that the cost to the body politic would soon become a heavy burden. History shows that trachoma has been one of the scourges of humanity for many centuries. The ancient Egyptians suffered from it four thousand years ago. The eyes of well preserved mummies offer unmistakable evidence as to its presence. Celsus, an ancient Roman, has left an excellent description of the disease as it existed twenty centuries ago. It seems to have had its origin in Egypt, and as the facilities for travel have increased, so also has increased its spread throughout the world. So contagious is the disease in the land of its origin, that but few of the natives escape an attack. Those who have visited Egypt have no doubt been struck with the enormous number of blind persons that are there encountered. Like most contagious diseases, trachoma flourishes where the rules of sanitation are least observed. In ancient times, the disease often became epidemic. An epidemic was started in Europe in the twelfth century, when the Crusaders, after warring with the Saracens, returned from the Holy Land. In 1798, when Napoleon opened his Egyptian campaign, some 20,000 of his troops are said to have contracted the disease. Many became blind, and the failure of some of Napoleon's subsequent ventures is ascribed to this affliction. When his soldiers returned to Europe, they started one of the most disastrous epidemics of which we have any record.

That epidemics are not confined entirely to ancient times is shown by the following extract which was taken from a letter received from Dr. Lederle, then Commissioner of Health of New York: "55,470 children were examined; 6,670 exhibited contagious eye disease, a percentage of 12; 2,328 of these were of the severest type of trachoma, necessitating almost immediate operation; 3,243 were trachoma of milder type. Some schools had as high as 22 per cent. of cases."

From the foregoing it will be observed that there was ample reason for placing trachoma upon the list of excludable diseases, and, furthermore, that the wisdom of the course was fully justified by subsequent events.

Favus, a contagious disease of the scalp and more rarely of the finger nails, was also placed on the excludable list. This affliction flourishes in the old-world centers, where filth and overcrowding attain their maximum. The early exclusion of this disease from the United States has been so effective that the disease has become so rare that the great majority of medical men have not even seen a case.

Leprosy and syphilis in its active stages, for obvious reasons, were at once placed in this category.

In 1901 cases of tuberculosis in which the tubercle bacillus could be found in the sputum were added to the excludable class. A number of medical men in the United States denounced this course as inhuman. However, when it is remembered that this disease is very communicable, that many of the immigrants would soon become public charges, that the United States Government is not a charitable institution for the afflicted of other countries, and that the introduction of each case adds just one more center of infection, it is believed that the majority of the profession will endorse that step.

Epileptics, idiots, and the insane are specifically mentioned by law, and since the two latter have been included by Congress in the three acts which have been passed since 1882, it may be safely assumed that the American people are fully convinced of the justice of the course.

The second class of diseases which come under the head of likely to become a public charge is a very long one. The examining medical officer certifies that the disease or deformity from which an alien suffers is likely to affect his ability to earn a living. Such certificate is not final. The immigrant is afterward taken before a board of special inquiry which is usually composed of three immigrant inspectors. If the immigrant can satisfy this board that he or she will not become a public charge, such person is released. The proof commonly required consists of furnishing a good and sufficient bond, by which the Government may indemnify itself in the event of its having to incur any expense in the immigrant's behalf. The most common disease for which rejection takes place is valvular disease of the heart. This class of cases has been a great burden upon the charitable institutions in the past, and it is quite natural that it should be so. The majority of the immigrants are laborers, and after a short period of the strenuous exertion which is required in America, they suffer from a rupture of compensation, and in many cases become a charge upon the community in which they reside for many years.

Hernia is another frequent cause of rejection. Two points are always considered in making a certificate for this condition: First, the immigrant's occupation and the extent to which the hernia is likely to affect the ability to earn a living; second, the probability of an early operation. In the latter case, application for treatment would probably be made at a charity hospital, in which event the alien would become a public charge for at least several months.

The list of diseases which come under this class multiplies itself indefinitely, but when it is considered that deformities and diseases like poor physique, chronic rheumatism, nervous affections, malignant tumors, senility, debility, defective eyesight, etc., may seriously impair the immigrant's ability to take care of himself, it is not difficult to understand why it should be so.

Another important matter from an economic standpoint, as well as being highly humanitarian, is the detection by the medical inspection of such persons as are suffering with temporary afflictions. Under this head come diseases like pneumonia, enteric fever, malaria, fractures, and any of the other acute medical or surgical maladies. Such persons are placed in the hospitals until they have recovered, at

the expense of the transportation company bringing them. The expense of such temporary treatment in the past has amounted to $20,000 for each 100,000 aliens that arrive.

In the Philippines, the same immigration laws apply as in the United States. Alien immigration has not been an important factor. During the fiscal year ended June 30, 1904, there arrived in the Philippines 6,111 immigrants. Of this number, 351 were rejected for medical causes, which is a percentage of 5¾. The rejections were nearly all made under the head of the absolutely excludable diseases. It would perhaps seem that in the examination of over 6,000 aliens, many more or less grave physical defects should have been detected. But, when it is remembered that with the exception of an insignificant few, the entire immigration that comes to the Philippines is Japanese, that they are nearly all male adults in the prime of life, and that this race is noted for its sound physique, the matter assumes a new aspect. Another important consideration is the fact that the tide of immigration to the Philippines has only begun. History shows that when immigration to another country commences, at first only the more robust individuals go, and after they establish themselves the weaker ones follow.

While there has been considerable discussion in the United States and in these islands as to the advisability of making the immigration laws of the Motherland apply in their entirety to the Philippines, yet very little has been said that could be construed as being unfavorable to the application of the medical features of the law. The matter may be viewed from two standpoints: First, whether there is any danger of infecting the inhabitants of the islands with diseases from which they do not suffer at present, and, second, from an economic standpoint. With regard to the introduction of communicable diseases, the ones most likely to be introduced would be trachoma and favus. Trachoma prevails only to a very limited extent among the natives, and such cases as do occur are usually of a very benign nature. If, then, the more virulent cases from other countries were allowed to come in freely, it may be safely predicted that its spread would be very rapid. Favus is also an uncommon disease among Filipinos.

The immigrants who are rejected on account of having various disabilities would only be a liability upon the country, and for that reason we are much better off without them.

In view of the foregoing, it may be said that the enforcement of the medical clauses of the immigration law has been of the greatest benefit to the Philippines, from both a humanitarian and a practical standpoint.

MASTURBATION IN CHILDHOOD.*

By AUGUST ADRIAN STRASSER, M.D.,

ARLINGTON, N. J.

Unfortunately, onanism in childhood and even in infancy is not so rare as it would seem, and occasionally we meet a case which astounds by its peculiarities and deviation from the accepted portraits of this affection, which we should look upon as a pedagogic error rather than dignify it by the title of what it only rarely becomes—a disease; and it is then that we are perforce driven to debate questions of therapy and of its antecedents, etiology and pathology. Generally having a direct causation in some form of local irritation, this affection, which is at first purely and simply a vice, may degenerate into an ineradicable physical condition, which, because of a secondary group of symptoms, may go on to a fatal termination, as I will show later. The sexual instinct being, as Darwin has so painstakingly shown, an instinct that rules the actions of all species, and affording decided advantages to the individual exhibiting it the earliest, we can discover it at times in man and animals in some form at very early ages, and in the former, when not directly the resultant of irritation, the vice is usually readily curbed by appeals to the moral sense, commands, instruction or directly punitive measures; however, as already said, at times we meet with a case in which it is impossible to influence the trend of the disease in any way. Whether under these circumstances we have to deal, as in the case I detail below, with a sort of dementia precox caused by the constant irritant action on one set of cerebral centers and a physical degeneration, or vice versa, the dementia is etiologically to be held accountable for the clinical manifestations we term masturbation must remain a moot question; it has given me the opportunity, however, of eliciting several points that may be interesting from a pediatric and psychological standpoint.

With this preamble, allow me to present to you the following case history in detail and then to return to my theme. On January 13, 1902, the stepmother, who was also the aunt, of the little patient, consulted me concerning the girl, Edith R. The child was nine years of age, robust and well nourished, despite the fact that she had practiced moderate autoonanism since her fourth year. Her previous history is not of moment; paternally no pathogenic tendencies; maternally a strongly tubercular tendency, in that her mother, several aunts and others of the family died of pulmonary tuberculosis. No specially neurotic history. After the death of the patient's mother, the aunt discovered the vice which the child had acquired during the mother's illness and promptly tried to curb it by threats and punishments, and it seemed that it was successfully eradicated from the brain of the still very young child. However, she was able in secret to continue the ill-conduct, as she later confessed, and whether it be true or not, the little patient boasted that she could remember to have practiced the vice as an infant. Recently the practice had been resumed with full force, so that because of the violent manual friction the nymphæ and the mucous membrane of the vaginal walls were red and inflamed, very much swollen and bathed with a yellow mucopurulent secretion. Perfectly frank and open, assuming an attitude of decided skepsis toward any and every attempt to describe to her the results of persistence in such practices, the child was entirely unaware of the gravity of her vice, and proved herself in no way amenable to reason. It was impossible even with gifts or promises to make her stop her vicious conduct. It was her boast that even while the physicians were talking to her she had elicited an orgasm and that they had not noticed it. At first she had to evoke the sensual climax by manual friction; then she turned her attention to the clitoris itself and she succeeded in elongating that organ to 2 cm. and to make it so hyperesthetic that even the sitting on the school bench or on a chair at home, with or without crossed legs, was sufficient to produce the orgasm. She did not hesitate about lying any more, and as she was very intelligent and able to reason logically far beyond her age, it was easy for her to evade the observation of anyone not having technical knowledge of her doings.

It was apparent, however, that lately the child was running down both physically and mentally; she was easily fatigued, ate scarcely enough to sustain life, partly because of anorexia, partly because

* Read by invitation before the Jenkins Medical Association.

she masturbated even at meal times. It was necessary to take her from school, since firstly she could not concentrate her faculties to the necessary extent, and secondly since she requested permission to go to the closets so often that it seriously interrupted classroom discipline and the suspicion arose and was verified by observation that she tried to induce other children to become votaries of the same viciousness. Ten to fifteen times a day, by her own statements, proved by observation unknown to her, she elicited a typical orgasm, with spastic movements of the vagina and a copious mucoid secretion. Under these conditions, even if it did not promise much, I thought that perhaps a clitoridectomy might avail something, since until now manual or instrumental friction were essential to produce the sensual climax, and inasmuch as the clitoris itself was the direct organ of contact used in its production. The parents decided to think the project over and I lost track of the case until the following March, when the patient was again presented to me.

The strong, robust child had become transformed into a tottering little old woman, with sunken eyes whose roving look gave her a haunted expression; with weak and flabby musculature, an ashy skin, in places cold and cyanotic; in short, a masturbator whom it was impossible to wean from her nasty vice. She was able now, since her father had essayed to stop the practice by tying her arms and legs far apart to the bedstead at night to reach her aim by other means. Firstly, by holding the urine until night and then so directing the stream that, as I was able to witness once, it flowed over and against the clitoris and provoked by its warmth erection and orgasm; and secondly, even this was no longer essential, inasmuch as by purely psychical efforts she was enabled to elicit sensual gratification. In the interval the child's parents had consulted Prof. Jacobi, and naturally under the present changed conditions and the much graver phenomena, as now only mental efforts were needed to masturbate, he advised against any and all operative interference and aside from the usual sedatives and tonic hydrotherapy could give no further advice. As both persuasive and punitive measures had proved themselves ineffectual in inhibiting the vice, and it had reached enormous proportions now, the child masturbating fifty to sixty times in the twenty-four hours, her mother decided to try the effect of constant supervision and by strict commands to change the trend of thought immediately whenever the patient showed any inclination to exercise her practices. This became an arduous and a hopeless task. For even while in the act of reading aloud there would be a sudden panting and sighing, and even before a word could be uttered the orgasm had been evoked. Thereupon the mother resolved to try another method. She stopped the child from sitting for the most part of the day and to inhibit the act of onanism while the child was standing she fastened an ordinary oblong breadpan between the child's legs in such a manner that it was an impossibility for her to put her legs together and by friction of the genitals between them to help her mental efforts at masturbation. Unfortunately not only did this not achieve the desired result, but, I have no doubt, tended to hasten the fatal outcome of the case indirectly, for though I had the pan removed as I foresaw what might result from its use, yet I was too late to prevent its ill effects altogether. For the child in her insane efforts to approximate her legs pressed with such force upon the sides of the heavy pan not only to bend them deeply but also pushed the edges so strongly into the inner aspects of the thighs, over Scarpa's triangles, that both the legs from the knees down were highly edematous and almost all the toes exhibited gangrenous areas. Naturally in a body whose resistance was so low and which was still further daily insulted by her uninterrupted practices and in which the circulation was more than sluggish, it was impossible to stem the progress of the gangrenous process, and after total separation of all the toes the patient succumbed to pyemia on December 24th.

During her illness, however, the patient showed these interesting psychological phenomena. Although well and sufficiently nourished, she would stealthily, if necessary by roundabout routes, no doubt suffering intensely from the condition of her feet, creep through a dark hall downstairs to the pantry, voraciously devouring anything she could lay her hands on, even what she had perhaps refused at supper-time; and quietly regaining her room, resume her masturbation and stoutly deny the theft in the morning. She willfully retained the urine by day and passed it in bed at night for the purpose of onanism; and so also held back the feces in the rectum, partly by its presence to aid in evoking the orgasm and partly as an adjunct in directing the stream of urine forward upon the elongated clitoris. All efforts to wean her from the evil having proved vain, it became necessary, partly as the stench from her feet became almost unbearable despite the greatest care, and partly because she persisted in attempting to lure her stepsister into the same evil habits, to put her into an isolated room, with plenty of fresh air and light, where, in spite of all means to save her from herself and the inevitably fatal termination of such actions, she gave herself up to the vice with almost maniacal activity. In the short (may I call them lucid?) intervals she spent her time in writing, and in a childish style and diction she wrote a sort of autobiography in which she warns other children who might be persuaded to travel the same road to take her as an example and a warning. By and by her former logical thinking began to waver, and the child presented a condition that clinically had all the earmarks of a dementia senilis. With an increasing cerebral paralysis, there were found spastic contractions of the legs and in the arteries it was not difficult to feel the typical thickening and hardening of an arteriosclerosis. Even though it necessitated almost superhuman efforts to elicit the results, yet the patient masturbated until a very short time before her death, going back to manipulation to accomplish the act.

This case seems worthy of some thoughtful study, and we may now return to our theme in general; and indeed let us glance for a moment at the etiology. It is a safe premise to look upon all masturbators, who are not so because of some hereditary taint, as in some way neuropathic. Nevertheless we must not forget that certain physical phenomena due to some external or internal irritant may at times be the etiologic antecedents of the trouble. So, *e.g.* pediculi, worms that have wandered from the anus into the vagina or under the prepuce, itchy skin eruptions, diabetes mellitus and, most frequently, ill-fitting clothing are the usual etiologic factors in the production of the vice, and if not curbed early unfortunately it rapidly enters the chronic stage. In addition to these, Rohleder, in his monograph, adds certain others which may at times be of great importance and may serve to clear up a dark point for the consequent therapeutics. He enumerates phthisis, leukemia, convalescence from an illness accompanied by high fevers, hemorrhoids, psychical and cerebral affections, at times menstruation, laziness and idleness as being causative agents within the body, and as etiologic factors in the environment he mentions wrong home and public education, an uncurbed, riotous im-

agination, improper nourishment, certain medication, business or social conditions, sexual abstinence, unhappy marriage, the fear of too large families, of venereal infection or of impotence, and religious reasons such as Moraglia has described, all of which, however, are of moment to the adult more than to the child; and I must emphasize once more the first group as being of importance not only to pediatric therapeutics but also as having great influence upon symptomatology. Unfortunately the symptoms of this usually secret vice are unknown not only to the laity, but also, what is worse, to many physicians. As typical of the affection in infancy the cases of Hirschsprung and Kraft are to be taken. The former reports one case in a child of 4-5 months of age and another one which the attending physician had been unable to diagnose. An apparently normal girl of 13 months, rubbed her pelvis back and forth against the nurse's breast, evincing more and more excitement constantly; the face became flushed and was distorted, and finally, accompanied by sighing and panting, the object of the act was obtained. During the attack the child was entirely apathetic to its surroundings and directly afterwards would sink into a deep stuporous sleep from exhaustion.

For older children of course the symptomatology depends upon the method by which the sensual gratification is achieved. Violent friction of the penis, clitoris or genital opening is continued to that point when, accompanied by hiccups or rapid breathing, palpitation of the heart and flushing of the face, the orgasm occurs. Or some children frequently accomplish their aim by tightly approximating their legs and wriggling back and forth upon their chair, the child meanwhile becoming more and more indifferent to its environment, its face being more and more distorted, the eyes fixed and glassy, until, with copious secretion of sweat, or even with a fainting spell, the sensual climax is reached and relaxation follows. As the vice is conducted in secret, preferably in outhouses or toilets, it is not easy to establish these symptoms. However, certain adventitious signs sometimes aid in clearing up an apparently inexplicable case. An unnaturally shy and reticent bearing, unwillingness to share in the play of other children, and if urged to do it invariably being the spoiler of the game, so that thus the time and solitude may be gained to practice the vice; the disgust evinced (alas, too seldom!) by the subject's playfellows; the noticeable habit of sitting quiet and daydreaming, which is contrary to robust child life; all these must warn us to be on the outlook, inasmuch as idleness is a prolific source of this naughtiness. Of course at first there are no great physical disturbances or mental vagaries. If, however, the vicious practices are continued, other local and systematic disturbances accompany the nervous symptoms, of which I need only mention the most usual ones. The child onanist is easily startled and frightened; frequent and causeless vasomotor disturbances are discerned in violent blushing; in younger children the occurrence of attacks such as were described above or which may even be masked under convulsive seizures obtains. Whether these attacks rest upon an epileptic basis of which the onanism is the outward manifestation, must still remain sub judice.

Local symptoms are, unfortunately, far from conclusive; if, however, the suspicion is rife, it is wise under some pretext to establish the facts by ocular inspection of the genitals. It is the rule to find the prepuce of masturbating boys much elongated, this with the retained smegma often being the causative agent in producing the vice. In little girls an elongated clitoris, a fissured or eroded hymen and red and inflamed mymphæ, a true vulvitis, are symptomatic phenomena; and in children of either sex the finding of pollutions by day or night, in fact the staining of the underclothes by any secretion must be highly suspicious and invite careful scrutiny, which must, however, be cautiously conducted, lest we overshoot the mark by suggesting the very evil which we are trying to undo. Among subjective symptoms we must mention the complaints of cerebrasthenia, dullness and slowness in the cerebral functions, causeless mental and physical fatigue, a depreciation of the vital forces, muscular weakness and a depression that often reminds one of tædium vitæ seen in melancholia. The circulatory and respiratory organs are frequently affected, anorexia obtains, and the rectal muscles are or become sluggish and it is not difficult to trace the portrait of the typical neurasthenic in the child.

As far as the pathology of the disorder is concerned, aside from the findings in the cerebellum and spinal cord in cases where the onanism was long and violently continued there is not much else to be described except the lesions we might expect from the described etiology and symptoms. Rohleder reaches the following conclusion on this topic: "Onanism like all sexual excesses rests upon violent sexual impulses, which are unsuccessfully combated by the subject and thus establish the vice, and is not necessarily caused by an abnormality or lesion of the spinal cord."

It would exceed the bounds of this essay to describe in detail the sequelæ of onanism in childhood; it must suffice if we examine its effects on character and morality, the adjuncts that will make the growing child an integral factor in the community. Luckily it is rare that masturbation is practiced so excessively as above described so that a condition resembling marasmus is engendered. Nevertheless lying and dissimulation are bad foundation stones for the building of character, and especially when all actions and sensations tend only to the one goal, the gratification of sensuality. The constant yielding to these impulses fosters a weakness of willpower and naturally this failing robs the masturbator of the power for concentration of thought or purpose. As Kraft-Ebing puts it: "Nothing equals masturbation at an early age in its aptness to dry up the wellspring of noble and ideal sensations that would naturally arise at that time of life in an individual with normally evolved sexuality. This defect influences adversely morality, ethics and character." Systemic changes as results of the evil practice are at first not discernible; if continued, however, the phenomena described above under symptomatology, especially those pointing to cerebral fatigue, can be elicited. Growth is frequently stunted, the organs of digestion and assimilation have their functions disturbed, and there is a gradual reduction from par in bodily vigor and health.

To give a certain prognosis or institute unfailing therapeutic measures is difficult, as much depends on how far the vice has progressed, what inroads on character and willpower have been made and naturally upon the ultimate causation. Certainly both prognosis and treatment can be more hopeful if the causative lesion is found in some itchy eruption than if the condition of satyriasis or nymphomania exists, which would entail the assumption of some psychical defect. It would be foolhardy to give a good prognosis in every case; however, on the other hand, scepticism must not allow us to refuse therapeutic measures in any case.

On the subject of treatment two points are worthy of discussion. The one, prophylaxis, is, to be sure, more of a pedagogic than a medical problem. The education of a child, the hygiene of school and home,

kind but strict supervision on the part of both parents and teachers, who should be constantly on the watch and aware that the child is readily induced by others to start the practice, these are all measures of inestimable value in preventive medicine. As difficult as the subject may be, it can only be right to explain the phenomena of puberty to children at that age and to warn them and protect them from abuse at their own or others' hands. With smaller children, of course, the conditions are different, and it is here that prophylactic measures are of supreme importance. Supervision of nourishment, clothing, cleanliness of body and associations, strict orders to nurses and attendants forbidding the handling of the genitals of their charges, the inculcation of chasteness upon the child even toward other members of the family, all are feasible during this stage of life when everything is still learned by imitation.

If, however, onanism is discovered as already existing in a young child, provided no physical lesion is the causative agent, a good thrashing or active punishment may be of service. With older children this measure must be judiciously considered, lest a more serious defect be established and from an onanist be evolved a sexual pervert. The exhibition of disgust and disdain, instruction as to the possible evil consequences of the continuation of the vice, strict supervision, a change of the trend of thought by inducing the undertaking of difficult and tiring tasks, and a tonic course of hydrotherapy are of more service here than the long lists of medicines, of sedative or tonic nature usually advocated.

SAW PALMETTO.

By I. L. VAN ZANDT, M.D.,
FT. WORTH, TEXAS

Some years ago the subject of this paper was brought to my attention through reading an article by an old physician who had long been under the necessity of using a catheter on account of prostatic trouble. This he had been relieved of by the use of saw palmetto. A recurrence of his trouble from "taking cold," had also been relieved. This particularly attracted my attention, because of being so entirely contrary to the general teaching, Sir Henry Thompson, for example, saying that we have no medicinal remedy for this, and all we can do is to teach such patients to use a catheter. Nowadays surgery seems to be about all that is recommended.

I began soon after prescribing it as occasion offered, for old men whose sleep was disturbed by the necessity of rising to empty the bladder. I do not think one of them failed to receive benefit. The fluid extract was used alone. One case, severe and with marked results from treatment, is here reported: Mr. B. B. was brought to me from Denton County, April 29, 1896. I saw him late in the afternoon. His physician, being unable to introduce a catheter, had aspirated his bladder once daily for four days, the last time probably on the morning of that day. Procuring a Mercier's elbow catheter (one with elbow near the point), I had but little difficulty in introducing it and drawing off the urine with a lot of disintegrated blood clot. I then cleansed the bladder with a boric-acid solution, by repeated small washings after the manner of Sir Henry Thompson. This was repeated morning and evening for the next two days, when the man became able to pass his urine during the day. It was necessary to catheterize him in the morning for five days more, after which he was able to pass his urine as necessary.

He took a drachm of the fluid extract four times a day at the beginning; later three times a day. He was at the beginning pale and emaciated. He remained about town for a month or more, by the end of which time his complexion was ruddy and he appeared to have gained much flesh. He told me he was in better condition than he had been for eight years, and wrote me, two or three months later, that his improvement had continued to that time.

Knowing that saw palmetto had been used in respiratory troubles, and considering the similarity between the prostate and the tonsils, I determined to test the remedy in chronic inflammation involving the latter. My first experiments (two patients) were made during the winter of 1892-3. One patient with tonsils very much enlarged, breathing through his mouth entirely, was greatly benefited by a short treatment. He moved away in a short time, and I lost sight of him.

The other patient, aged four or five years, was under medical care for his throat every few weeks during the winter. I treated him in one acute attack, then put him on saw palmetto, and though I have continued to do the family practice, I have seen him only once since with a sore throat.

Since that time I have given the treatment to many cases. Some of the patients received marked benefit to throat and to general health; others failed, some probably from lack of persistence in taking the medicine.

I will conclude with a short report of cases: Girl, æt. about 10. Has chronic trouble with throat; has had much local treatment; is subject to frequent attacks of spasmodic or catarrhal croup; I saw her in one of these attacks in August, 1903. She was given apomorphine muriate and potassium iodide for immediate relief, and then half-drachm doses of fluid extract of saw palmetto three times a day. I saw her about a year later. She had not had another attack of croup. I was consulted as to the propriety of her taking another "course" of the medicine to strengthen her against attacks the coming winter, and advised her doing so.*

Boy, æt. 7. was taken to one of our best throat specialists on account of snoring. He could not sleep except propped up, and even then his breathing could be heard in the next room with the door closed. The specialists gave no hope for relief except by operation for enlarged tonsils and adenoids. He could not, however, promise absolute immunity from danger of death, so the operation was declined. As I was the family physician, I was asked to prescribe. I gave the saw palmetto, and in a short time he could lie down and sleep without a pillow, making no more noise than the healthiest babe. All this time one nostril had been "running," but this ceased after several weeks taking of the medicine, and now his nose and throat give him no trouble whatever.

Young woman, æt. 16, had been under a specialist's care for chronic sore throat for one month without benefit. I found her with an acute attack. This was relieved and she was put on saw palmetto. Her mother tells me her throat is better than for years.

*This patient has passed another winter without an attack of croup, and her general appearance has very much improved.

Theory of Light Treatment.—Strebel (*Dermatologische Zeitschrift* Bd. XI, 1904) believes the chief action to be one of stimulation to the trophic nerves involved; a second beneficial action may arise by the products of the destruction of albumen acting upon the pathogenic microorganisms as poisons.

MEDICAL RECORD.

THE ACTION OF ALCOHOL ON THE CIRCULATION.

THE somewhat conflicting and contradictory statements made by different observers and investigators with regard to the physiological effects of alcohol render it difficult for the unprejudiced student and critic to formulate a satisfactory opinion in the matter. The subject is not merely of academic interest, but it has a most important practical bearing, for alcohol has long held a prominent place in the fields of dietetics and therapeutics alike. We are now concerned with what may be designated the legitimate use of alcohol, as contradistinguished from its excessive use or abuse. As in other affairs, it is not easy to define where the one ends and the other begins, and with respect to alcohol, as to other therapeutic agents and to foods, the individual tolerance varies widely. It is difficult to believe that a body that has had the sanction of continued usage for so long a time as alcohol can be entirely unnecessary and useless.

Two opposing views are at present held as to the physiological actions of alcohol, the older one that it is a stimulant and the latter one that it is a narcotic. The evidence would seem to show that neither is entirely correct or wholly wrong, but that certain functions are energized, while others are inhibited as a result of the influence of alcohol. Some light is thrown on this phase of the subject by the results of an investigation reported by Drs. Horatio C. Wood and Daniel M. Hoyt at the recent meeting of the National Academy of Science and published in abstract in the *University of Pennsylvania Medical Bulletin* for May, 1905. In experiments on normal, uninjured dogs it was found that, as a rule, alcohol in small or in large dose, by inhalation or by intravenous injection, caused no increase in arterial pressure, although occasionally such an effect appeared to be produced. An explanation is wanting for the latter fact. Similar results were observed after subcutaneous injections of alcohol in dogs suffering from an infective fever, and they are in accordance with clinical observations on patients suffering from various infective fevers.

When the general vascular system was separated from the dominant vasomotor centers by section of the spinal cord in the cervical region, with maintenance of the respiration, the arterial pressure was distinctly and consistently increased. When the aorta was ligated in the middle thoracic or upper abdominal region the effects produced by alcohol were so unsatisfactory, because of the enormous disturbances of respiration and the general system resulting from the operation, that no conclusion could be safely reached.

Observations made with the aid of the current-meter showed that small amounts of alcohol caused marked increase in the rate of blood-flow through the large arteries, quite independently of and unrelated to the arterial pressure. This increase was consistently maintained on repetition of the intravenous injection, until finally the rate gradually lessened and became subnormal in consequence of vascular paralysis.

The work of the isolated reptilian heart was markedly and persistently increased by addition of from ¼ to ½ per cent. of alcohol to nutritive fluid fed to the viscus, while addition of from ½ to 1 per cent. gave rise at first to increase in the amount of work followed in a short time by a marked lessening in the amount.

In attempting an interpretation of the experimental facts detailed it is pointed out that the arterial pressure is a result of the interplay of two antagonistic forces, namely, the propelling power of the heart on the one hand and the frontal resistance of the blood vessels on the other hand. If either of these be increased, the arterial pressure will rise, and, conversely, if either be diminished, the pressure will fall. If one be increased and the other diminished, the arterial pressure may remain unchanged, or rise or fall, in accordance with the degree of the forces in operation. The fact, therefore, that alcohol does not constantly elevate the blood-pressure is no proof that it does not stimulate either the heart or the blood vessels, as it may stimulate one dominant factor of the blood-pressure and depress the other in such a degree that the balance is maintained. The want of constancy in the influence of alcohol upon the blood-pressure suggests a disturbance of the dominant blood-pressure factors, of such a character that the balance between these is not always accurately maintained.

It is further argued that the increase in the blood-pressure produced by alcohol after paralysis of the vasomotor system as a result of section of the cervical cord cannot be due to a local action on the walls of the blood vessels, as it does not occur before the section. This disparity seems to indicate that alcohol consentaneously stimulates the heart and depresses the vasomotor centers. This conclusion is strongly corroborated by the increase in the rate of blood-flow in the arteries induced by alcohol. Such a result can be brought about by augmenting the force of the propelling power or by diminishing the frontal resistance or by a combination of both of these factors. If it were due simply to stimulation of the heart the blood-pressure would rise, while if it were solely the outcome of vascular depression the blood-pressure would fall. Further corroboration is afforded by the increased amount of work performed by the reptilian heart under the influence of small amounts of alcohol. Plethysmographic observations on human beings also indicate the occurence of dilatation of the blood vessels as a result of the action of alcohol.

In conclusion it is pointed out that there is at present no sufficient evidence that alcohol is a direct cerebral stimulant, such as is caffeine and that, so far as consciousness is concerned, its tendency is to induce sleep rather than wakefulness, while the cere-

bral excitement and increased mental activity that follow upon the ingestion of alcohol are to be attributed to the increased flow of blood through the vessels of the brain.

PARATYPHOID FEVER AND ITS CLOSELY ALLIED AFFECTIONS.

In the University of Pennsylvania Medical Bulletin for April, Dr. Herbert Fox traces the relations of and classifies in order, typhoid fever, paratyphoid fever, paracolon infection, and meat poisoning.

The first account of paratyphoid was in 1896, when Achard and Bensaude isolated from the urine of one case, and pus of an abscess at the sterno-clavicular articulation of another, organisms which were practically identical. In Paris Widal in 1897 found this organism in an abscess in a phthisical patient. Gwyn in 1898 and Schottmüller in 1900-'01 contributed reports of supposed typhoid cases from the blood of which they obtained paratyphoid organisms. According to Dr. Fox the reported cases now are approaching a hundred.

As a rule paratyphoid fever closely resembles in its clinical course typhoid fever, but striking aberrations sometimes occur. Libman's case is an example. In this case the disease assumed the picture of an acute cholecystitis which began suddenly with nausea, vomiting, prostration, followed by distention of the abdomen and pain in the epigastrium and right hypochondrium, and jaundice. From the gall-bladder by aspiration and at operation, and from the blood, Libman was able to cultivate paratyphoid organisms. Two types of paratyphoid organisms are recognized, known in the laboratory as "A" and "B" types.

The conclusions reached by Dr. Fox are as follows: 1. Paratyphoid fever differs from typhoid fever in (*a*) a shorter invasion and rise of temperature; (*b*) shorter or absent period of continued fever; and (*c*) marked diurnal remissions of temperature, much deeper than in typhoid fever and without periodicity. An absence of the Widal is suggestive, if it persist in reasonably high dilutions. 2. The duration is on the whole shorter than that of typhoid fever and in the cases in which type "B" was adjudged the etiological factor, this fact is more striking than in the type "A" cases. 3. The general findings of the type "A" cases are nearer to the typhoid than type "B," the latter presenting a picture more like septicemia. 4. The complications of type "B" infections are more numerous, more purulent, and the course is more fulminating in these cases. 5. The causal germs belong to the intermediates of the typhocolon series, the type "A" being nearer to the bacillus of Eberth and Gaffky, while type "B" approaches the meat-poisoning group. 6. The clinical evidences of the respective organisms just named agree with their general properties and relations to infections in this order, ranging from the subacute typhoid to the hyperacute meat poisoning. 7. Antityphoid serum will clump the paratyphoid "B" at the same time as with the *B. typhosus,* sometimes even in higher dilutions; so that a positive reaction of a patient's serum to both *B. typhosus* and *B. paratyphosus* "B," even if the latter be in higher dilutions, will not permit a diagnosis. On the other hand, only twelve times in 94 cases of typhoid fever did the serum react with the type "A" paratyphoid, so that a positive reaction with type "A" and not with the bacillus of Eberth may be taken as nearly a proof of the existence of an "A" paratyphoid infection. 8. It is probable that there is some other factor responsible for coagglutinations than an increased value of the agglutinins normally present in the blood. 9. The best proof of the existence of a para-infection is the isolation of the bacterium and the saturation test.

The Growth of Cancer.

Dr. R. E. F. Bashford, General Superintendent of Research, and Director of the Laboratory of the Imperial Cancer Research Fund, recently delivered an address on the growth of cancer, published in *The Lancet* of April 1. He points out that the subject of the growth of cancer has been neglected. Investigators of the eminence of Thiersch, Waldeyer, and Cohnheim paid little attention to the matter and would seem to have overlooked its great importance. The explanation of this apparent indifference, according to the writer, is the simple one that the processes of cell division were little understood by the older investigators, who had also little information on fertilization and on the development and differentiation of organisms to guide them in studying the normal growth of the human body, and far less still to help them to comprehend growth in the aberrant form presented by cancer. As the result of his latest investigations Dr. Bashford summarizes as follows: "Cancer is identical in all vertebrates, and in growing accommodates itself in a striking manner to the time limitations imposed by the compass of life in different animals. Under favorable experimental conditions the growth of cancer is undefined, of enormous and, so far as we can judge, limitless amount. Artificially propagated cancer displays all the characteristic features of the growth of sporadic tumors. The growth of artificially propagated cancer is due to the continued proliferation of the parenchyma cells." The author claims to have confirmed this conclusion, originally advanced by Jenssen. "The artificially propagated parenchyma makes the reaction of the host subserve its own needs. Artificially propagated tumors cause no symptoms in the organism to which they have been added. The power of differentiation is definitely in one direction only, even three and one-half years after separation from the original host. The balance of evidence is in favor of the growth being interrupted, and not uniform and continuous." From the standpoint of therapeutics the investigations of the Imperial Cancer Research Fund have established the early surgical treatment of cancer upon that experimental and rational basis which has hitherto failed. Artificially propagated tumors produce metastases as do sporadic tumors. Sufficiently early removal of the local transplanted tumor removes metastasis from the region of possibility, and the immediate practical outcome of the whole investigation is a strong experimental justification of early operation in cancer.

Pinto.

Dr. Paul Wooley, Director of the United States Serum Laboratory at Manila, reports, in a recent Bulletin of the Bureau of Government Laboratories, on the above-named affection. A group of dermatomycoses, characterized by peculiar nonpigmented patches on the skin, in the scales from which hyphæ or spores or both, of a mold-like fungus are found, is known under the terms paño blanco, pinta, pinto,

caraté, mal pintado, mal de lòs pintos, mal de pinto, cute, cativi, pannus, and the spotted disease of Central America. This epiphytic disorder has been reported from Mexico and Central and South America; another disease resembling it in some respects has been observed by Legrain in North Africa and by Sandwith in Egypt, but, to Dr. Wooley's knowledge, no previous report has come from the Philippine Islands. The case reported by Dr. Wooley was that of a Filipino laundryman, 15 years old, and in good health. The patient had pinkish white patches, irregular in size and shape, on the ankles, dorsa of the feet, shins, elbows, hands, wrists, and one on the right shoulder. The largest ones were over the external malleoli of the ankles. No two of these patches were of the same size or shape, nor were they distinctly defined, but they shaded from their clear white centers to the normal brown of the skin. Neither were the lines of extension regular, so that the outlines of the patches were irregular and crenated. About the larger areas were smaller ones, some barely visible andf of a faint pinkish white or very light brown color. On palpation it was evident that the skin over the larger patches was slightly rougher than the normal, and it felt somewhat thicker. The palpating finger could detect no abnormal variation in the covering of the smaller spots. There was but a minimum amount of scaling, and there was some itching. From an examination of scrapings from one of the larger lesions on the ankle in a solution of caustic potash, the nature of the disease was rendered plainly evident, while on close examination Dr. Wooley states that the clear white spots with almost normal looking skin can be confused with no nother skin disease with which he is acquainted.

War Against Secret Nostrums.

Few words are needed to convince sane men of the evils of indiscriminate dosing with secret remedies—the catarrh cures, nerve tonics, and restorers of menstrual irregularities with which the druggists' shelves are loaded and the advertisements of which aid so effectively in the dissemination of moral teachings by giving financial support to the religious press. Physicians, in general, are too busy to undertake a crusade against the sale of these alcoholic compounds, as many of the most popular and most advertised preparations are, and they are also a little timid in taking up the cudgels in a fight in which it would be claimed they were trying to down a successful rival. It has been reserved for Mr. Bok of the *Ladies' Home Journal* to do most commendable work in exposing the evils attendant upon the promiscuous sale of these secret medicines, and he has suffered much vexation, in consequence, through suits brought against him by irate patent medicine manufacturers. He feels, however, that all the labor should not be his, and calls upon the medical profession for aid in his warfare upon quack remedies. In a communication to the *Journal of the American Medical Association*, he points out that if a successful crusade against injurious patent medicines is to be carried on, the medical profession, as a whole, must take a strenuous part in the fray, and that each and every one should do his share in suppressing the evil. The secret medicine interest is powerful and well endowed with the sinews of war. Thus it has happened that in all the States save one, bills designed to regulate the sales of injurious patent medicines have been doomed to ignominious defeat. The principal supporters of these bills have been members of the Women's Christian Temperance Union, who have hurt the cause for which they fought by ill-considered zeal and lack of discretion. Their efforts, therefore, have been well meaning, but ineffective. Mr. Bok calls upon the members of the medical profession to make united effort to curb the sale of hurtful secret remedies by legislation, and declares that if this be not done it will be a clear case of shirking responsibility. It is obvious that so long as the physicians of the country show themselves apathetic in the matter, the sale of secret medicines will continue, and the proprietors will wax fat and flourish exceedingly. For the sake of the public, therefore, if not in their own interests, it would seem that medical men should bestir themselves to down the nostrum evil.

News of the Week.

Meeting of the Trustees of the United States Pharmacopeia.—The fifth annual meeting of the Board of Trustees of the United States Pharmacopeial Convention was held at the Philadelphia College of Pharmacy, May 13. The members present were: Dr. J. H. Beal, Scio, O.; Mr. Albert E. Ebert, Chicago; Prof. Joseph P. Remington, Philadelphia; Mr. S. A. D. Sheppard, Boston; Dr. H. M. Whelpley, St. Louis; Dr. H. C. Wood, Philadelphia. In the absence of the chairman, Charles E. Dohme, who is in Europe, Vice-Chairman Beal called the meeting to order. The minutes of the fourth annual meeting and the intervening correspondence of the board were read and approved. It was decided that a sample page or pages of new books in which it is desired to use some of the text of the Pharmacopeia shall be submitted to the chairman or acting chairman for approval before permission to use pharmacopeial text be given. Prof. Remington, chairman of the Committee on Revision, made a detailed report of the progress of the work, and stated that the new Pharmacopeia would be out before the end of June. The action of the chairman in fixing August 1, 1905, as the date from which the new revision will be official was approved. One hundred unbound copies will be distributed simultaneously to pharmaceutical and medical journals for review purposes. All books paying for the use of pharmacopeial text will be required to print upon the obverse of the title page the following words in full-face or black letter type: "Authority to use for comment the Pharmacopeia of the United States of America, Eighth Decennial Revision, in this volume, has been granted by the Board of Trustees of the United States Pharmacopeial Convention, which Board of Trustees is in no way responsible for the accuracy of any translations of the official weights and measures or for any statement as to strength of official preparations." The subject of a Spanish edition of the Pharmacopeia was reported upon by President Wood. He was instructed to continue his investigaion and again report to the board. Dr. Wood finds considerable demand for a Spanish edition of the United States Pharmacopeia in Cuba, Mexico, Costa Rica, and Porto Rico. The Rice Memorial Fund Committee made a final report. Mr. S. A. D. Sheppard was appointed a special committee of one to take charge of this fund and deposit the same in the name of the Board of Trustees of the U. S. P. Convention. It was decided that, as soon as sufficient monies shall have been received after paying present indebtedness and current bills, the sum of $200 be paid to each member of the Committee on Revision excepting the chairman (Prof. J. P. Remington), to whom shall be paid $2,000; to the secretary of the Board of Trustees (Dr. Murray G. Motter), $500; and to the

treasurer of the convention (Dr. George Wythe Cook), $200. The secretary of the board reported progress on the Abstract of Proceedings of the Board of Trustees, and further action was postponed. The following officers and standing committees were elected for the ensuing year: *Chairman,* Charles E. Dohme, Baltimore, Md.; *Secretary,* Dr. Murray Galt Motter, Washington, D. C.; *Executive Committee,* Dr. J. H. Beal, Scio, O., chairman; Dr. H. C. Wood, Philadelphia, and Mr. Charles E. Dohme; *Auditing Committee,* Dr. H. M. Whelpley, St. Louis, Mo., chairman; Dr. A. E. Ebert, Chicago, and S. A. D. Sheppard, Boston, Mass.

The West Virginia State Medical Association held its thirty-eighth annual meeting in the Board of Trade Hall, Wheeling, W. Va., May 24-26, 1905. The following papers were read: "The Teachings of Failures," by F. L. Hupp, Wheeling; "The Palliative Treatment of Prostatic Hypertrophy," by H. E. Sloan, Clarksburg; "Preoperative and Postoperative Treatment of Surgical Cases," by J. E. Cannaday, Paint Creek; "Appendical Abscess—Pathology and Treatment—Report of Cases," by S. M. Mason, Clarksburg; "Injuries of the Head—Report of Cases," by Henri P. Linsz, Wheeling; "Anatomical and Physiological Principles Involved in the Symptomatology of Brain Traumatism," by J. Schwinn, Wheeling; "Office Treatment of Rectal Diseases," by William M. Beach, Pittsburg; Symposium on Pneumonia: "Etiology," by S. S. Wade, Morgantown; "Pathology," by L. O. Rose, Parkersburg; "Symptoms and Signs," by W. W. Tompkins, Charleston; "Treatment," by L. D. Wilson, Wheeling; "Tuberculosis," by J. W. Preston, Keystone; "Pseudo-Membranous Croup," by S. W. Bush, Parkersburg; "Cases and Experiences of Interest," by W. H. Sharp, Parkersburg; "Diseases of the Kidneys," by M. McNeilan, Parkersburg; "Rupture of the Bladder," by J. R. Cook, Fairmont; "The Importance of Early Diagnosis of Intraocular Lesions," by H. R. Johnson, Fairmont; "Fikker's Diagnosticum," by L. O. Rose, Parkersburg; "Drugs and the Diazo Reaction—A Communication," by William W. Golden, Elkins; and "Notes on Tuberculosis," by Andrew Wilson, Wheeling. Webster Springs was chosen for the next place of meeting, and the following officers were elected: *President,* S. S. Wade, Morgantown; *Vice-Presidents,* G. W. Bruce, Moundsville, F. L. Hupp, Wheeling, and A. S. Grimm, St. Mary's; *Secretary,* William W. Golden, Elkins; *Treasurer,* V. T. Churchman, Charleston; *Councillors,* A. O. Flowers, Clarksburg, A. R. Warden, Grafton; W. W. Henne, Quinnimont, W. N. Burwell, Parkersburg, T. W. Moore, Huntington; *Delegates to American Medical Association,* J. L. Dickey and L. D. Wilson of Wheeling.

Merger of Medical Colleges.—Arrangements have been consummated for the consolidation of the Kansas City (Mo.) Medical College, the Medico-Chirurgical College of Kansas City, Mo., and the College of Physicians and Surgeons of Kansas City, Kan. These schools will be merged and a faculty chosen which will become the medical department of the University of Kansas. This department will be located at Rosedale, Kan., a suburb of Kansas City, Mo., and instruction will be given in both Rosedale and Kansas City, Mo., advantages for clinical teaching being more abundant in the latter city. In St. Joseph, Mo., the Ensworth Medical College and the Central Medical College have combined, the institution retaining the name of the Ensworth Medical College.

A Special Class for the Treatment of Pulmonary Tuberculosis among Negroes has been started at the Department of Health's Clinic for the Treatment of Communicable Pulmonary Diseases. This class will be held on the evenings of Tuesday, Thursday, and Saturday of each week from 8 to 9 P. M., and only negroes will be seen on those days and hours. The establishment of such a class was due to a request made by the Afro-American physicians of this city, they believing that the colored people would attend such a special class more readily. The physicians in attendance are negroes, and arrangements have been made for the services of a colored nurse. The physicians are: Dr. P. A. Johnson, laryngologist; Drs. W. H. Johnson, A. A. Kellogg, A. S. Reed, J. F. Thorpe, and E. P. Roberts, attending physicians. These physicians were recommended by the Medico-Chirurgical Society (colored), New York City, at a special meeting on June 4. Treatment and medicines are, of course, free, and the patients will be visited at their homes by the tuberculosis nurses of the Department. Negroes may attend any of the other classes of the Clinic, which is open daily from 9 to 4, and on Monday, Wednesday, and Friday evenings from 8 to 9 P. M.

Future Pursuits of Columbia's Graduating Class.—Statistics of the graduating class of Columbia University, announced at the class day exercises on Monday of this week, show that fifteen members of the class of 1905 have prepared at college for commercial life. Twenty have decided to try their fortunes at the bar, while nine will teach, but medicine has fallen off in an unusual manner. Only five men in the entire class, which numbers over 100, will follow this profession. As a rule, law and medicine lead.

American Medical Society for the Study of Inebriety and Alcohol.—The thirty-fourth annual meeting of this society will be held in the hall of the Atkinson School Building, Portland, Ore., July 12 and 13, 1905. The president's address, by Prof. W. S. Hall of the Northwestern University of Chicago, Ill., will be a review of the progress of the study of the action of alcohol during the year. The committee on the Influence of Alcohol in Literature and History will present a report by its president, Dr. John Madden. The committee on Heredity as a Cause in the Disease of Drug and Spirit Taking, will report, and the committee on Patent Medicines will also submit a statement of their work. The second session will be a memorial service to the memory of the late Dr. N. S. Davis, and a continuation of a similar meeting of the American Medical Association.

American Laryngological, Rhinological, and Otological Society.—At the eleventh annual meeting of this society, held in Boston, June 5, 6, and 7, 1905, the following officers were elected for the ensuing year: *President,* Dr. James E. Logan of Kansas City, Mo.; *Vice-Presidents,* Drs. Thomas H. Halsted of Syracuse, N. Y., William L. Ballenger of Chicago, Ill., H. Bert Ellis of Los Angeles, Cal., and Henry L. Myers of Norfolk, Va.; *Secretary,* Dr. Wendell C. Phillips of New York; *Treasurer,* Dr. Ewing W. Day of Pittsburg, Pa.; *Councillors,* Drs. Frederic C. Cobb of Boston, Mass., James F. McKernon of New York, and H. W. Loeb of St. Louis, Mo.

American Neurological Association.—The following officers were elected at the annual meeting of this society, held in Philadelphia June 1-3, 1905: *President,* Dr. Henry L. Stedman of Boston; *Vice-Presidents,* Drs. Henry M. Thomas of Baltimore, and George W. Jacoby of New York; *Secretary and Treasurer,* Dr. Graeme M. Hammond of New York; *Councillors,* Drs. William G. Spiller of Philadelphia, and Walter Channing of Boston.

American Laryngological Association.—At the recent meeting of this association, held at Atlantic City, June 1, 2, and 3, 1905, the following officers were elected: *Preident,* Dr. J. W. Gleitsmann of New York; *Vice-Presidents,* Drs. J. L. Goodale of Boston and C. W. Richardson of Washington; *Secretary Treasurer,* Dr. James E. Newcomb of New York.

Hospital Fires.—A small fire that started in the cellar of the J. Hood Wright Hospital last week was discovered and put out before it had gained headway enough to do much damage. Owing to defective insulation, what might have been a serious fire started in the diet kitchen of Ward 22, in Bellevue Hospital, late one night last week. Through the efforts of the night nurse, whose hands were badly burned, the blaze was kept from spreading till help arrived.

Motor Runs for Convalescents.—It is announced that several members of the New York Motor Club purpose making regular visits to the various hospitals in the city to take out for a run in the country those among the patients who are strong enough to be about and to stand the trip, but not well enough to leave the hospital.

State Hospital Boards Named.—Boards of managers for the eight State hospitals have been appointed under the new law re-establishing such boards. The law restores the system of control in force three years ago, and substitutes for the boards of visitation that existed since then boards of managers, which have general supervision over these institutions excepting their finances. They are required to meet once a month and report. Many of the members of the old boards of institutions have been appointed as members of the new boards of managers.

Diplomas Withheld from Medical Students.—The Faculty of Georgetown College, Washington, D. C., has voted to withhold diplomas from eleven seniors in the medical department for cribbing in their final examinations. The difficulty grew out of the protest of the class against being examined in medical zoology, because they had been unable to get text books on the subject. The Faculty insisted and the students thereupon felt at liberty to inform each other and to get what help they could from outside to pass the examination in this branch.

St. Gregory's Free Hospital, at 91 Gold street, New York, a new hospital for the treatment of accident cases alone, was opened on June 8. Before the day was out it had three patients. All three walked into the hospital for treatment, and were attended by the House Surgeon, Dr. C. H. Duncan. Attached to the hospital are two ambulances, neither of which was called out on the first day.

Radium Rays in Hydrophobia.—According to despatches from Milan, Professor Tizzoni, of Bologna, has succeeded in curing rabies in animals by means of exposure to radium. After injecting into rabbits virulent hydrophobia virus, he subjected them periodically for several days to the influence of radium rays. The rabbits thus treated were, he declares, all cured, while others, likewise inoculated but not subjected to the cure, died of hydrophobia. A pinch of salt, as well as of radium, is indicated here.

An Ex-Christian Scientist with a Thought and a Demonstration.—Dr. Charles G. Pease, a dentist, and formerly one of the most enthusiastic of Christian Scientists, has sent in his resignation as a member of the "First Church of Christ, Scientists," and has coincidently published a book entitled "An Exposure of Christian Science Methods and Teaching Prevailing in the First Church of Christ, Scientist, New York City." The sub-title of the volume runs: "and of the dangers of the philosophy which has protected, supported, and enabled its votaries to deceive, falsify, oppress, persecute, practise dishonesty, and do works in fulfilment of the prophecy recorded in Matthew 24: 24, constituting a menace to individual liberty and rights and to the moral and spiritual life of a nation."

St. Louis Hospital for Consumptives.—The Health Committee of the House of Delegates, St. Louis, has recommended the erection of a building on the outskirts of the city to be used especially for the care and treatment of tuberculous patients.

Obituary Notes.—Dr. Jacob Price died at Westchester, Pa., on June 9 at the age of seventy-eight years. His ancestors were Friends, who settled in the State with William Penn. He was graduated from Jefferson Medical College in 1850.

Dr. Melville M. Shearer, for many years county physician of Sonoma county, California, died on May 28 at his home in Santa Rosa, at the age of sixty-two years. He was a graduate of the College of Physicians and Surgeons, Keokuk, Iowa, in the class of 1864.

Dr. Hatton N. T. Harris, of the U. S. Navy, died of appendicitis at Pensacola, Fla., on May 19.

Dr. Joseph Wishard died at his home in Greenwood, Ind., on May 31, at the age of seventy-seven years. He was a graduate of the Medical College of Ohio in 1857. He was a member of the Indiana State and of the Johnson County Medical Societies.

Dr. William Isaac Goodin of Cincinnati died May 31 at the age of sixty-nine years. He was a graduate of the Medical College of Ohio in 1874.

Dr. William E. Maloney died at his home in Keene, N. H., on June 1, at the age of forty years. He was a graduate of the Medical Department of the University of Vermont in the class of 1887.

Dr. John William Compton of Evansville, Ind., died at Terre Haute on May 29, at the age of eighty years. He was a graduate of the Medical College of Evansville in 1873. He was for four years president of the Indiana State Medical Society.

Dr. W. K. Spiller of Bridgeport, Ala., died May 26, after a long illness. He was a graduate of the Medical Department of the University of Nashville in the class of 1874.

Dr. Amasa J. Mullen of Indianapolis died May 30, at the age of thirty-four years. He was born in Delaware, Ind., and was graduated from the Central College of Physicians and Surgeons, Indianapolis, in 1875.

Dr. Henry Wagner Kreider of Galesburg, Ill., died on May 25, at the age of eighty-five years. He was born in Washington county, Pennsylvania, and was graduated from the Rush Medical College, Chicago, in 1856.

Dr. August F. Hipp of Toledo, Ohio, died on May 24, at the age of sixty-five years. He was born in Germany, but came to this country with his parents at the age of ten years. He was a graduate of the Cincinnati College of Medicine and Surgery in the year 1870. He retired from active work several years ago on account of failing health.

Dr. Arthur H. Gardner of this city died suddenly on June 12, at the age of thirty-seven years. He was born in Springfield, Mass., and was a graduate of the College of Physicians and Surgeons, Columbia University, in the class of 1898. He served as interne in the German and the Sloane Maternity hospitals and was physician to the Presbyterian Hospital and the Vanderbilt Clinic.

Correspondence.

THE AMERICAN MEDICAL ASSOCIATION. WAS IT REORGANIZED ON CORRECT PRINCIPLES, AND WILL IT, UNDER METHODS PURSUED, ACCOMPLISH WHAT IT OTHERWISE MIGHT?

To the Editor of the Medical Record.

Sir:—In my previous article the fact was developed that the American Medical Association has, after five years of effort to reorganize itself and to adopt a new constitution, made no progress whatever, standing in these respects just where it stood in 1900. It is true that four editions of a document, alleged to be a new constitution, are in existence, but any one who will make the proper investigation will become convinced beyond the remotest doubt that these editions are of no validity whatever. Although they are invalid, it is worth while to subject them to some analysis and study in order to find out what would have been the organic law of the Association had any of them been legally and constitutionally adopted.

Before beginning this study, however, it is pertinent to inquire: Why so many editions of the new constitution, and in such rapid succession? Are not the fundamental principles which should underlie organization, and which should be embodied in a constitution, fixed and immutable? It there not a philosophical method according to which these principles should be framed into a constitution? Cannot all of the details be so incorporated as to render frequent alterations and amendments unnecessary? Is not the entire vocabulary of the English language available in which to formulate principles and details, and, if so done, where the necessity for asking annual permission "to make verbal and other alterations?" Neither have the changes in the successive editions been slight. On the contrary, they have been radical and numerous, as may be seen by comparing each succeeding edition with the preceding one.

Although affirmative answers must be given to all of the interrogatories propounded above, yet one year seems to be the limit of longevity of an edition of the "New Constitution." Beginning with 1901, three editions are already in their graves, and it remains to be seen whether the fourth will follow its predecessors. Is this not a high degree of mortality among infant constitutions? Does it not indicate that some inherent vice of *constitution* must exist?

These rapid transitions—reminding one of moving pictures—cannot be ascribed to any change in the personnel of the "Committee on Constitution," for the identical committee of three, appointed in 1900 to prepare a revision of the old constitution, has retained, and still retains, a monopoly of "Constitution Architecture."

To close the discussion of this point, it may be broadly and confidently affirmed that whenever a Constitution for the American Medical Association is philosophically and logically written and put in clear and definite language, it will be good for all time, with perhaps an occasional amendment as to secondary principles and as to details. To analyze with any degree of thoroughness the four editions would be a long and tedious task—hence some only of the vulnerable points will be dealt with; many will be left untouched.

Inasmuch as the verbiage of a constitution is an element of great importance, and inasmuch as the committee has, at several meetings of the Association, received special permission to alter and perfect this, it would seem legitimate to subject the words and the syntax of the instrument, along with the principles embodied, to fair and unprejudiced criticism.

The caption of the 1902 edition is: "Constitution or Articles of Incorporation." How one and the same instrument could be a "Constitution and Articles of Incorporation" stands in urgent need of explanation, for in this instance the terms seem to be employed as synonymous.

Article 2 in all of the editions is practically the same, some very slight changes of verbiage only appearing. In the last edition the caption of this article is, "Object." Without quoting the paragraph, it may be said that one object only is set forth, but in rapid succession this one object becomes subdivided into seven purposes. As these seven purposes continue to string themselves out, one after another, the mind of the reader is severely taxed to maintain the connection between the governing word and the successively stated purposes, until long before the end of the paragraph is reached all connection is lost and the mind of the reader drifts, rudderless.

Inasmuch as "object" and "purpose" mean one and the same thing, wherein consists the economy of words, or the advantage of construction, in naming one object and then dividing it into seven purposes? Why not set up seven objects at once? It would be a severe reflection on the English language were the construction of this article not susceptible of very great improvement. Not only is the construction of the article open to objection, but one of the purposes named therein should be expunged forever, and never permitted to pollute the constitution of any organized medical body. The purpose alluded to is "of safeguarding the material interests of the medical profession." Whenever any medical organization proclaims that one of its objects is to protect the material interests of its members, it drags itself down to the level of a trade-union organization, and smirches and blackens and destroys the proud traditions of which the profession has boasted for two thousand years. It may at times become necessary for the members of the profession to protect their material interests by some combined movement, but when such a necessity arises they should meet as individual doctors, and not as members of the organized profession. Let a sharp line of demarcation be always drawn between the two fields of action. Besides, the question of material interest varies according to locality, and must always do so, hence this is strictly a local question, to be managed by all of the doctors of a locality, including those outside of the organized profession, as well as those inside. It is both impracticable and unethical for the American Medical Association to undertake to legislate with reference to the "material" interests of the profession. Both policy and equity, therefore, dictate that the purpose quoted above be forever expunged from our national organic law.

Articles 3 and 4 of the latest edition of the alleged constitution would be decidedly improved in sequential arrangement were their order reversed, then, the term, "constituent associations" would not be used in advance of its definition.

Article 4 is open to many and serious objections. To take up some of them: Evidently this article proceeds upon the false idea that the American Medical Association is the parent of the State associations, when, in truth, the opposite is, or ought to be, the case, irrespective of the chronological order in which organization takes place. Suppose for a moment that the State organizations should discontinue sending delegates to meetings of the American Medical Association, what would happen? Evidently, the organization would at once die. Article 4 reads as follows:

"Those State and Territorial medical associations which have, or which hereafter may, become organized in accordance with the general plan of organization of the American Medical Association, and which have declared by resolution their allegiance to the said American Medical Association, and shall agree with other State and Territorial Medical Associations to the formation and perpetuation of the House of Delegates of the American Medical Association, shall be recognized as Constituent Associations."

Observe the wording for a moment, and a very remarkable requirement may be noted, to wit.: State and Territorial Medical Associations in affiliation with the American Medical Association are required to agree with *other* State and Territorial Medical Associations to the formation and perpetuation of the House of Delegates. What are the *other* State and Territorial Medical Associations with which agreement must be had? If organized bodies in affiliation with the American Medical Association must agree on certain points with *other* organized bodies, it necessarily follows that the latter must be outside of, or not affiliated with, the American Medical Association. Is the meaning what the words plainly indicate, or is it not that the State and Territorial Medical Associations in affiliation with the American Medical Association must agree among themselves in reference to certain points? Whilst this is very likely the intended meaning, yet most surely the words do not express it.

Further, to require that State organizations shall declare allegiance to a national body they themselves have created seems to be conspicuously illogical and superfluous. If the State organizations did not desire a national body, why should they create one? Or is it meant by declaring allegiance that a State organization shall not under any circumstances have the right to withdraw from the national association? If this be the meaning, then how is this clause of the constitution to be enforced? If it cannot be enforced, then why insert it? Again, why require that the State organizations shall commit themselves unqualifiedly "to the formation and perpetuation of the House of Delegates?" The House of Delegates, as has been repeatedly said, constitutes essentially the Association in its corporate capacity. Such a requirement, therefore, is tantamount to asking the delegates to commit themselves to themselves. Some things go without saying, and this seems emphatically to be one of them.

Article 5 provides for a "House of Delegates," and calls it "a business body." Whilst a more felicitous expression than "business body" might be found, yet that is a matter of taste, rather than of principle. In the preceding article

(4) the State and Territorial Medical Associations are made the constituent associations of the American Medical Association, yet in Article 5 the House of Delegates is made merely "a business body" *of* the American Medical Association—that is, at one time the House of Delegates constitutes the American Medical Association; at another time, it constitutes only a part of it. According to the basis laid down, the delegates should essentially constitute the Association, yet in Article 5, and in other places, the "House of Delegates" is spoken of as a body different and apart from the Association, a kind of *tertium quid*. Evidently, fundamental confusion exists here. In fact, the term "House of Delegates" is liable to be misleading. The truth is, the delegates representing constituencies should be the Association in so far as managing its business affairs is concerned, and all other members should be allowed to participate in scientific work, with full privileges of the floor when scientific subjects are being dealt with. Of course, this is practically the case now, but the point raised is that from a legal and logical standpoint the delegates representing State organizations constitute the Association in its corporate existence, and should never be spoken of as a *part* of the Association.

Article 5 limits the total voting membership of the House of Delegates to 150, and provision is made in the by-laws for a reapportionment of delegates each third year. Suppose, by virtue of increased membership in the State organizations already affiliating with the Association, the number of delegates had reached, or very nearly reached, the maximum allowed (150), and suppose further that at a meeting following one during which a reapportionment had been made, a number of delegates from newly organized State Associations should apply for admission, what would be done with the delegates in excess of 150? Under the procrustean rule laid down, they could not be admitted to a meeting of the Association until after another reapportionment, which, under the circumstances stated, would be two years off. Would it be wise to keep newly organized State bodies unrepresented that long? Certainly not. Why not then fix the basis of representation at such ratio as would, so far as could be judged, keep the House of Delegates within a wieldy size? Whenever it increased beyond that, the size could be cut down by enlarging the basis of representation—that is, making it one delegate to eight hundred or one thousand active members. Such a plan would certainly escape the danger of bringing about such a dilemma as that mentioned. Far better permit the number of delegates to exceed 150 temporarily than to keep newly organized State Associations waiting two years for another apportionment before they could secure representation. Wherein consists the necessity or wisdom of arbitrarily fixing the number of delegates at 150? Twenty-five above or below that number would not matter, seeing that the size of the House of Delegates could always be regulated by regulating the ratio of representation.

Article 7 of the constitution reads as follows: "The House of Delegates may create such branch organizations as may be deemed essential to promote the welfare of the medical profession." For vagueness and indefiniteness, the above article could hardly be excelled, certainly not in any other constitution. The questions that must be asked and answered in order to enable one to find out what this article means, and whether he favors it or not, are these: What kind of branch organizations is meant? How shall they be created? What relation shall they sustain to the parent body? What to one another? What rights shall they have? What duties shall they perform? What responsibilities shall be imposed upon them? What dues shall they pay? What is meant by the "welfare of the medical profession?" Is it the material, moral, or scientific welfare that is to be promoted? What good will be accomplished by organizing branch associations? One of the unwritten laws in regard to making constitutions is that the words in which they are written must carry their own interpretation, and not need outside explanation. Tried by this standard, the above article is certainly very obscure.

Article 9 deals with Officers, very imperfectly, however, and by specifying who the *general* officers are to be, leaves us to infer that *special* officers are yet to be mentioned. This article provides that no member of the House of Delegates shall be eligible for the office of president or vice-president. Whilst the motive back of this provision is obvious, and, in a sense, praiseworthy, the logic of it is very faulty indeed. Think of it! An organization denying to the men who are most closely identified with it, who are most responsible for carrying out its policies, the privilege of holding the very offices that confer the greatest power of promoting its welfare. It is doubtful whether a parallel to this provision exists in the constitution of any similar body. But, leaving out the logic of the matter, such a provision is, from a practical point of view, open to very serious objection. Eminence in the profession has very naturally hitherto constituted, and will probably always constitute, the qualification that will win the presidency. Unfortunately, often such qualification is not combined with a knowledge of parliamentary law or with familiarity with the duties of a presiding officer. Who that has served in the House of Delegates has not painfully seen the disadvantages under which such a president labors? Having perhaps never served in the House of Delegates himself, being unfamiliar with its methods of procedure, and possibly unfamiliar with the constitution and by-laws, he is largely helpless and powerless. In addition to all these disadvantages, he must endeavor to conduct the business of the House under an inexact and inadequate constitution, and with a poorly established order of business. Is it strange that the result should be a very chaotic condition of things, unsatisfactory to the president himself and to every person concerned? Is not this condition of things driving away from the House of Delegates many of the best men in their respective States? Who is there who has not frequently heard delegates remark in disgust: "I am never coming back here again."

Such a condition of things loudly calls for remedy. Men should esteem it an honor and not a hardship to serve in the House of Delegates. The remedies are clear and definite:

1. Construct a logical and correct constitution;
2. Prescribe a proper order of business, and adhere to it;
3. Elect the first and third vice-presidents from the House of Delegates, and make long service therein a prominent qualification for either one of these positions:
4. Provide that the president, aided by the second and fourth vice-presidents, shall preside over the Association when assembled in general session to hear addresses, to deal with scientific subjects, etc., leaving to the first and third vice-presidents the duty of presiding over the House of Delegates.

Under such a system order would soon be evolved out of chaos, legislative work would be attended to systematically and orderly, and delegates would not go away from a meeting with a mental or avowed resolution never to come back again.

Article 10 deals with the board of trustees, but very briefly. This body will be discussed under the by-laws.

Article 11 has as a caption "Funds," which is a unique term in such connection. The terms "dues," "revenues," and "appropriations" are common enough in connection with similar constitutions, but "funds" must be original. Original as is the caption, the article itself is far more so. Indeed, it is perhaps without a parallel. The first clause in the article says: "Funds shall be raised by an equal assessment of not more than ten dollars annually on each of the members." Why not call it "dues," as is done in all other similar bodies? The next clause reads: "Funds shall be raised from the Association's publications, and in any other manner approved by the board of trustees." Passing by the indefiniteness of the term, "the Association's publications," which is in a measure defined in the by-laws, the climax is undoubtedly reached in the latter part of the clause by giving authority to the board of trustees to raise funds in *any manner it may approve!* Is not this a very wide stretch of authority, and could not the board resort to very questionable and improper methods of raising funds, and yet be acting in strict accordance with the constitution? The only charge that might be brought against the board, so far as the writer knows, in adopting means for raising funds, consists in permitting advertisements to be accepted by the *Journal* that ought to bring a blush of shame to every member of the Association, when he turns the front or back pages aside to uncover the splendid scientific matter within, and that ought to stultify the exalted position upon which they as members of the profession have already claimed to stand. But this matter having been ably handled by others, the writer leaves it without further comment than to say that if the *Journal* cannot be maintained without such advertising, let it go down and be forgotten.

The final article in the latest edition of the constitution provides for its own amendment. The principles embodied in this article are sound, and, if adhered to, will prevent such hasty and inconsiderate action in dealing with constitutions as has occurred in the past.

Did time permit, a review of some of the provisions of earlier editions of the "new constitution" would be made. One of the most conspicuous of these, by reason of indefiniteness and impracticability, was the provision for a "Referendum." Although retained through two or more editons, it has now disappeared, it is hoped, forever.

The by-laws are, like the constitution, vulnerable at many points, and will be reviewed in another letter.

OUR LONDON LETTER.

(From Our Special Correspondent.)

CELEBRATION OF CENTENARY OF THE MEDICAL AND CHIRURGICAL SOCIETY—PNEUMONIA IN TYPHOID FEVER—SPLENOMEGALIC POLYCYTHEMIA—MEMORIAL TO R. A. M. C.—HOSPITAL BAZAAR—AMALGAMATION OF [illegible] HOSPITAL—GENERAL MEDICAL COUNCIL—OBITUARY.

LONDON, May 26, 1905.

THE centenary of the Royal Medical and Chirurgical Society has been duly celebrated this week. Monday was the centenary day, and at 5 P. M. the president (Sir Douglas Powell) held a reception at the society's house, delivered an address and admitted the new honorary fellows, viz., Sir W. Ramsay, Drs. Christian Bohr, Robert Barnes, and W. H. Gaskell.

In the evening there was a banquet at the Hotel Cecil, when H. R. H. the Prince of Wales occupied the seat at the right hand of the president and signed the roll as an honorary fellow. In proposing the loyal toast, the president spoke particularly of the claims of H. R. H. to their homage as the first member of the royal family who had accepted their honorary fellowship. The Prince replied in an effective little speech, which every one present could hear, giving thus an example of distinct delivery which many of the fellows would do well to follow, and affording a reminiscence of his father's fine voice and clear enunciation.

In proposing "The Society," the president gave a condensed account of the advances in medicine and surgery during the centenary, and mentioned a few of the names that have left an indelible record of their share in these advances.

"Literature and Science" having been proposed by Dr. Pye Smith, and replied to by Sir Conan Doyle and Sir William Haggins in characteristic speeches, the guests were duly toasted and the Lord Chief Justice gave the president, who duly acknowledged the compliment, and the festive dinner was at an end.

On Tuesday evening the society met to continue the celebration of the centenary, and at the same time pay its tribute to Marshall Hall, to whom we owe the first accurate conception of reflex action. The Marshall Hall address was entrusted to Dr. Henry Head, who took as his subject the "Afferent Nerves Under a New Aspect," and opened it by saying he hoped to remove the barrier which has always existed between the sensory nerves of the body wall and those of the sympathetic system. The view submitted to the society is the result of researches carried out by Dr. Head in conjunction with Dr. W. H. Rivers and Mr. James Sherren. Its importance may be judged by the words of the mover and seconder of the vote of thanks. The former, Dr. Ferrier, spoke of it as revolutionary, but certain to receive favorable attention which he believed would lead halfway to its eventual acceptance. The latter, Dr. Gaskell, said it put on a new basis, which would be understood, the question of trophic nerves.

The conversazione on Wednesday evening was, in the opinion of some, the most brilliant part of the celebration. It was held in the Natural History Museum, perhaps the best locality existing for such a purpose. Prof. Ray Lankester evidently enjoyed the task of explaining to visitors some of the treasures of the museum. The model of the diplodocus, lately presented by Mr. Carnegie, naturally attracted great attention, and among the distinguished visitors observed examining it was Senor Garcia, whose centenary was so lately celebrated. He passed about an hour in the museum. The music and other attractions may be mentioned as never excelled in similar entertainments.

An interesting historical exhibition was held in the society's house from Monday to Thursday inclusive, and attracted numerous visitors. A centenary volume has also been produced, in which are portraits of the deceased presidents with biographical sketches and extracts from their contributions. Altogether this centenary celebration has been an interesting one.

A case of typhoid, complicated with lobar pneumonia, communicated to the Clinical Society by Dr. S. P. Phillips and B. H. Spilsbury, is interesting, as the complication seems to have been due to the bacillus typhosus. The necropsy showed numerous typhoid ulcers in various stages in the intestines, but were perforated; the lower lobe of the left lung was in a state of red hepatization and white nodules were scattered throughout which looked like tubercles, but were found to be minute abscesses in which were masses of organism, some having the appearance and reactions of b. typhosus. The lung and the microscope slides were shown, and Dr. Phillips remarked that pneumonia, in the course of typhoid, was mostly due to pneumococcus, or staphylococcus, and very few cases had been recorded as due to b. typhosus. No one present could add cases in which the bacillus had been found in the lung, but several were mentioned which clinically commencing as pneumonia ran the course of typhoid—some in which infection was noticed. It is, perhaps, uncommon to see typhoid with [illegible] but the temperature curves were characteristic. One member mentioned a case of meningitis due to the typhoid bacillus.

Dr. F. Parker Weber read an elaborate paper at the Medico-Chirurgical Society on a case of "splenomegalic" or "myelopathic" polycythemia with true plethora and arterial hypertension, with cyanosis. I hope the description will give you a definite idea of the case. The patient was a Jewess, aged 37, admitted for acute erythromelalgia of the left foot. The case differs in the absence of cyanosis from others recorded, but Dr. Weber believes it is of the same nature, though at an earlier stage, and occurring in a fairly robust woman whose circulatory system is acting efficiently. He would therefore include for the present all such cases, with or without cyanosis, under the heading "splenomegalic polycythemia," although the spleen need not be obviously enlarged to clinical examination in every case. The blood was first examined in March, 1904, and polycythemia found. The woman under observation until February, 1905, is practically recovered from the erythromelalgia, and so not confined to bed, but the other symptoms, objective and subjective, remain, and with them the paper dealt. In a former paper, in conjunction with Dr. J. H. Watson, Dr. Weber related another case (*Internat. Clinics*, 1905) in which most extensive changes in bone marrow were found after death, and Dr. Parkes thinks the evidence is now conclusive that the symptom-complex of these cases is mainly due to a pathological activity in bone marrow, though it is not certain that this is the primary factor. The development and connection of the symptoms, Dr. Parkes suggested to be as follows: (1) Increased erythroblastic activity involving a great part, but not necessarily the whole, of the bone marrow; (2) increased viscosity of the blood, resulting from the polycythemia; (3) dilatation of small blood vessels, partly to lessen resistance to the viscous blood, partly to permit its dilution; (4) "plethora vera" or "polyhemia" to compensate for increased viscosity and the excessive percentage of the total blood volume occupied by the cells; (5) arterial hypertonia, a result of the strain on the circulatory mechanism; (6) cyanosis when it occurs, probably due to inadequacy of the series of compensatory changes which precede.

Dr. P. Stewart and Dr. G. A. Gibson sent letters, which were read by the secretary. The former described a similar case to that detailed in the paper; the latter stated objections to a mechanical theory of causation.

Dr. J. S. Haldane agreed that the facts pointed to increased activity of bone marrow. He did not think increased plasma necessary, and referred to the extraordinary constancy of the ratio of hemoglobin and the total blood volume to the body weight under different conditions. Yet in the case related, the volume was nearly double the normal, so that the patient's condition resembled that of an animal into which blood from another animal had been injected. He suggested that copious bleeding might benefit such cases.

Dr. A. J. Whiting, referring to the enlargement of the spleen in this condition, said that experiments on animals showed that after copious bleedings the bone-marrow became hypertrophied, and the spleen swollen and of a rosered color, hardly distinguishable from bone-marrow under the microscope.

Dr. Boycott, who had examined the case, said that apart from increase in hemoglobin and in the number of cells, he found an alteration in the size of the cells, some being larger, others smaller, than normal. The staining reaction, too, was altered, and a small number of nucleated red cells were constantly present. The polymorphoneutrophite cells were always present in a high percentage.

Dr. William Ogle, J.P., consulting physician to the Derbyshire Royal Infirmary, died on Tuesday, in his eighty-second year. He was a Cambridge graduate, M.A., 1851, M.D., 1858., Fellow of the R. Coll. Physicians, 1868. He was author of "Thoughts on Social Science" and contributor of various papers to the journals.

On Wednesday, which was "Empire Day," being the birthday of the late Queen Victoria, the King unveiled a memorial to the members of the Royal Army Medical Corps, who lost their lives in the Boer war. The monument was subscribed for by the officers and men of the corps, and is a Cornish granite obelisk on a semicircular wall of the same material and stands on a commanding site at Aldershot. Beneath the obelisk is a bronze group, nearly life-size, representing an officer and man of the corps tending a wounded soldier. On the wall tablets record the names of the victims of the campaign in South Africa, and the inscription on the obelisk is "To those who gave their lives for their country." The King expressed his pleasure and gratification in unveiling the memorial of the gallant officers and men who fell or died from disease in the late campaign, and declared he was well aware of the services rendered by the corps to their country and to the sick and wounded.

A three days' historical bazaar on behalf of the West-

minster Hospital has been a successful and fashionable entertainment, Dean's Yard, lent for the occasion, being transformed into an animated and fairy scene. A member of the royal family opened the bazaar on each day, the Duke of Connaught on Tuesday, Princess Louise on Wednesday, and Princess Henry on Thursday. On Wednesday there was an interesting concert in connection with the bazaar, and Sir F. Bridge gave a lecture on Elizabethan music and ancient instruments. On Thursday there was a march past by a number of ladies in the costumes of different periods.

Amalgamation being in the air, it is not surprising that the medical schools should be thinking once more about it. For many years a strong party has held that the number of our schools should be reduced, and that the earlier subjects of the curriculum might well be entirely separated from the hospitals. A step in this direction has been taken by the Westminster school, which has arranged for its students to take the preliminary and intermediate subjects at King's College. The later and clinical work will be continued at the Westminster, the staff of which can concentrate their attention on these subjects. I hear that several of the other schools are seriously pondering over such a step.

The managers of the Queen's Jubilee Hospital object to recommendations of the King's Fund Committee, and instead of carrying out their undertaking to abide by the result of the inquiry they invited, have issued a reply controverting the conclusions reported to them.

They do not recognize that the hospital as such is not wanted, and do not see why the staff or themselves should be dissolved. The King's Fund Committee would have reduced the hospital to a casualty and out-patient department. Even that is not required, and it would be well if the institution ceased to exist in any condition. The profession has never approved of its establishment, and its career has only been a blot on our list of charities.

The General Medical Council met for its eighty-first session on Tuesday, when the new president, Dr. MacAlister, delivered an opening address, a function which many of us hoped he would have taken occasion to discontinue. He reported that, according to the resolution of the council, he had sent a communication to the Privy Council respecting the abuses caused by medical and dental companies. At the request of the lord president, detailed evidence was supplied. He remarked that during this summer the cycle of visitations and inspections of final examinations would be at an end, and a general report on the whole series published as soon as possible. The pharmacopœian committee, with the assistance of the pharmaceutical societies, had appointed a committee of reference in pharmacy to which questions could be referred for investigation and report, and the hope was expressed that in due time a revised pharmacopœia, adequately representing the best pharmaceutical science and practice, would be produced. As to companies with misleading titles, the Privy Council had stated that an injunction could be applied for to prevent them from remaining on the roll of joint stock companies. The executive committee did not think in the absence of legislation the title of licentiates of the Apothecaries' Society could be altered in the register. Votes of thanks to the president, the director-general of the army medical service, and of the sister service, with other formal business and the appointment of committees, occupied the rest of the sitting.

Col. H. Comerford, who retired from the army medical service three years ago, died last week at the age of 61. He was in the Zulu war of 1879 and took part in the defense of Pretoria in 1881, for which he was mentioned in dispatches. For a year or two he had been suffering from insomnia, and used at times to give himself subcutaneous injections of morphine. He came to London for a change and was found unconscious in his room in a hotel and taken to Charing Cross Hospital, where he died. He had with him morphine solution, but no syringe, and it was suggested that having left it behind he had taken a dose by the mouth and miscalculated the amount. He had no trouble, and no reason exists for supposing his death was other than as the coroner's jury found, due to misadventure.

Dr. G. R. Slade, who only graduated last year, died on the 15th inst, at the London Hospital, where he had been appointed resident receiving officer and assistant anesthetist. He was 33 years of age.

Welander's Sack in Lues.—After three or four injections of mercurial oil the "sack" is substituted. This consists in a cotton bag large enough to cover the whole of the chest region with the open extremity above. Before applying each morning this is turned wrongside out and smeared well with ten grains of mercurial ointment upon the side worn next the skin. This is suspended about the neck, after turning the mercury side in, and worn for the twenty-four hours. The course of treatment extends over a period of six weeks to two months. For infants one grain of the ointment is sufficient.

Progress of Medical Science.

Boston Medical and Surgical Journal, June 8, 1905.

The Surgery of Renal and Ureteral Calculi.—The paper of A. T. Cabot is based on personal experience. He mentions the symptoms due to the arrest of the stone, and the conditions in the kidney and ureter favoring this arrest. In nine cases of ureteral arrest, one was at the junction of the upper and middle thirds, two in the lower part of the middle third and six in the lower third. When a stone is caught at the last-named point there is considerable chance of dislodging it by manipulation. In such cases, the ureter should be stripped from above downward as thoroughly as possible. If the stone remains in situ too long, abscess may result. This happened in two of the author's cases. If a ureteral stone cannot be dislodged by manipulation, it may be approached through the bladder if it projects into that viscus. The *x*-ray gives the exact location in any given case. The cystoscope is also a valuable aid in diagnosis. The author closes by referring to some of the approved operations which are in vogue in the surgery of this class of cases.

The Diagnosis of Renal and Ureteral Calculi.—Out of 3,708 autopsies at the two Boston hospitals since 1896, B. Tenney has found 16 recorded cases of renal and 8 of ureteral calculi, the 24 instances occurring in 21 patients. There is no special differences as to frequency between the sexes. From the symptoms of the condition in general we can make two classes of cases. In class 1 the patient suffers acutely and is in bed or desiring to go there. In this class we may have cases due to suffering from the passage down the ureter of a sharp-angled concretion or from an increase of pressure within the kidney or ureter. In class 2 we find a consciousness of more or less pain in one side in recurring attacks, general depression and the effects of anuria. Left sided attacks are not so difficult to diagnosticate as are right side attacks. The presence of a tumor in the region of the kidney may be due to a hydronephrosis from a kink in the ureter, to stoppage of the ureter by blood-clots or stone, to a pyelonephrosis or to a new growth. The absence of a tumor points more strongly to the presence of a stone in the kidney. On the right side the diagnosis is still further complicated by the fact that the symptoms may arise from the presence of a stone in the bile-ducts or appendiceal colic, and if the pain is located vaguely or near the middle of the abdomen, it may be produced by any of the causes of acute intestinal obstruction, or by the presence of a concretion in the pancreatic duct. If the patient be a female and the pain be referred to the pelvic region, there is a possibility of confusion with a tubal pregnancy. Nothing constant is shown by uranalysis. The temperature is generally a little elevated and there may be a slight leucocytosis. The presence of tenderness and muscular spasm over the left kidney may be characteristic. After recovery from an attack of the first type, the patient may pass into he second type and suffer from time to time from pain, colic, hematuria, pyuria, lumbar tumor, troubles in urination, tenderness over the kidney and pain in the external genitals. As to the value of the *x*-ray in diagnosis, the author's conviction is that the positive diagnosis is more reliable than the negative one so far as testimony from radiographers is concerned, but the personal experience of surgeons he finds to be just the reverse.

New York Medical Journal, June 10, 1905.

Hypodermoclysis.—W. P. McIntosh discusses the modern theories of immunity and claims that a proper understanding of this matter is necessary in order to appreciate the advantages and indications for hypodermoclysis. He finds that saline solutions in the manner indicated, cause an increase of both the erythrocytes and leucytes. It is also probable that the activity of the ductless glands is increased. Clinical histories are given of two cases treated. The author's personal experience extends to hemorrhage, shock, uremia, puerperal, eclampsia, typhoid fever, pneumonia,, anemia, and rheumatism., both muscular and articular. The clinical effects of hyperdermatoclysis are to raise the blood pressure, and to strengthen and regulate the pulse. The increase of the erythrocytes enables the blood to carry more oxygen, and the respirations are deeper and less rapid; the blood and tissues are more thoroughly oxygenated; the skin becomes moist (and warm if cold before). Diuresis is increased; the mind becomes clearer, sleep is promoted, the appetite is improved, the patient is encouraged, and there is a feeling of well being.

Medical News, June 10, 1905.

Drainage After Laparotomy.—L. A. Ewald believes it a settled question that drainage is no longer indicated in the so-called unclean cases when a considerable quantity of non-infectious material finds its way into the abdominal cavity. Also when malignant tumors are only partially extirpated or when a portion of a cyst wall is left behind,

he considers drainage not only unnecessary but even dangerous. We can more easily get rid of pus and suspicious fluid with cotton wipes than with drainage. If the pus is very virulent we must expect the worst, for most of such cases will die with spreading peritonitis. It is an utter impossibility to thoroughly drain the abdominal cavity with all its intestinal loops forming innumerable small cavities. Patients will be best guarded against danger by the observance of these precautions: (1) Through careful indication for operation and operative procedure. All those cases which show a severe infection through high temperature and other symptoms should be operated upon only when operation is made necessary by *indicatio vitalis*, and then a preliminary vaginal incision should be made. We know that pus located intraperitoneally or in the parametrium is highly infectious. (2) Through selection of proper time for operative procedure. Pus from a pyosalpinx is sterile after nine months. When no immediate indication for operative interference exists, it is better to wait. (3) Through careful observance of the following preventive measures: Protection of the abdominal cavity with layers of gauze; careful separation of adhesions; removable of all visible pus; exact hemostasis, and rapid operative procedure.

"Sore Throat," as Caused by Systemic Conditions.—N. G. Ward dwells on some of the complications following the ordinary tonsillar affections, circumtonsillar abscess and general systemic disorders. He says that there is a type of sore throat caused by faulty elimination. Waste products circulating in the blood cause the superficial vessels to contract. Hence arise the chilly sensations of the patient. Rheumatism is a frequent cause of the trouble, but the manifestations of the rheumatic poison are many, and must often be looked for in distant organs. Muscles subjected to prolonged strain are liable to be the seat of pain during atmospheric changes. Consequently singers and speakers are prone to chronic sore throat and hoarseness. Thy symptoms complained of in all cases of faulty elimination are apt to be out of all proportion as regards their severity to the slight local change in the appearance of the throat tissues. The treatment of this class of cases is obvious. It must be prompt and thorough. Neglect will lead to tissue changes in the sub-mucous layer and contraction of a permanent nature will follow. The blood-vessels will be pressed, and the vascular supply gradually cut off. Finally the epithelium and the mucous glands atrophy. Then we have a permanent condition, which no treatment will alleviate.

American Medicine, June 10, 1905.

The Lloyd Reaction for Morphine and Other Alkaloids.—Daniel W. Fetterolf says the blue-violet color produced in the play of colors when strychnine is treated with sulphuric acid and potassium dichromate, is also yielded by a mixture of the alkaloids, morphine, and hydrastin when acted upon by the same reagents. This fact was discovered by John Uri Lloyd, who said: "An amount even so small as 12 mg. gives violet vividly, and from 1 mg. or less it can be seen." The experiments made by Dr. Fetterolf show the delicacy of the tests is much greater. So small an amount as 0.02 mg. of the mixture, composed of 0.01 mg. of each of the alkaloids, yielded, under certain conditions, a pale blue-violet in the play of colors. The mixture of hydrastin and morphine may be recovered from animal tissues in amounts sufficient to produce the Lloyd reaction. The quantity by weight of the mixed alkaloids, hydrastin, and morphine recoverable from animal tissues, also the amount absorbed by and eliminated from the living animal tissues, is under investigation. Mixtures of apomorphine hydrochloride and hydrastin stirred with sulphuric acid, or with sulphuric acid and potassium dichromate, yield colors somewhat resembling those produced by mixtures of morphine and hydrastin; the brilliancy of the colors, however, being greater than with morphine and hydrastin, and having a greater delicacy of reaction. While there is some similarity of colon reaction, when a mixture of hydrastin and morphine is treated with sulphuric acid and potassium dichromate, the greater permanency of the violet color, preceded by a pink-brown and a final brown color, and especially the fact that such a mixture treated with sulphuric acid alone, yields a violet color, would serve to distinguish the mixture from strychnine. Therefore, it is unlikely that this color reaction should be mistaken except by a novice, for that which is produced with strychnine.

Observations Upon Amebas Infecting the Human Intestine, with a Description of Two Species, Entamœba Coli and Entamœba Dysenteriæ.—Charles F. Craig says that from his observations the following conclusions are warranted: (1) The intestine of man may be infected with two varieties of amebas, one patogenic (*Entamœba dysenteriæ*), and the other non-pathogenic (*Entamœba coli*). (2) *Entamœba coli*, the non-pathogenic variety, is found in 65 per cent, of healthy individuals studied, and in 50 per cent. of individuals suffering from diseases other than dysentery, if a saline cathartic has been administered. (3) These organisms can be easily distinguished in both fresh and stained specimens. (4) They differ widely in their method of reproduction, and this is the most important method of distinguishing them. (5) Entamœba dysenteriæ, whether fed in milk or injected through the rectum, produces in kittens the typical lesions of amebic dysentery as observed in man. (6) In kittens, Entamœba coli, whether fed in milk or injected through the rectum, is absolutely harmless. (7) Neither feeding experiments nor rectal injections of fecal material or the bacteria occurring in such material produces any of the lesions of amebic dysentery, unless *Entamœba dysenteriæ* is present.

The Bacterial Element in Catharsis.—Groesback Walsh calls attention to the fact that we have every reason to believe the increase in peristalsis, the increase of gas formation, and the liquefaction of feces which follow the use of cathartics is due to the same cause which produces the infections of the intestine, an exaltation in bacterial activity. He emphasizes that while cathartics differ in effects, these differences are only relative and the evidences on clinical grounds of a common agency of force are overwhelming. The following classification of cathartics is proposed: (1) Cathartics which produce a convulsion of activity amongst our intestinal bacteria by the production of an effusion of warm blood serum into the lumen of the gut. (2) Cathartics which act by means entirely unknown to us at the present time.

Journal of the American Medical Association, June 10, 1905.

Dyspepsia.—F. B. Turck considers dyspepsia one cause of national decay, hence its importance, not only to the individual, but to the State. He describes the mechanism of digestion and shows how it depends on proper fulfillment of the functions of gastric secretion and motility and how these depend on the general integrity of the splanchnic circulation which itself may be deranged by disorders of the gastrointestinal tract, thus producing the vicious circle seen with many intestinal and gastric lesions. This connection of the circulation is very important in the treatment. If any one of the tripod—motility, secretion, and circulation—is disturbed, dyspepsia is the result. The quantity and quality of the food, the times of eating, etc., are specially important in this connection, and in the treatment must be first considered. When dietetic measures fail, however, on account of infection of the stomach from pyorrhea or nasopharyngeal catarrh, for example, other measures must be resorted to. The stomach may also be overloaded, and its muscles lose their power, with consequent stagnation and fermentation, and the various cardiac and other general symptoms of the condition. Here lavage may be directly remedial in removing the load and in stimulating the gastric peristalsis. When the mucosa is colonized with germs, however, simple lavage or even gastric douching may not suffice to remove them. He advises the use of a double stomach tube for this purpose, the inlet tube with fine perforations, and the outlet with larger ones thus projecting jets with considerable force against the gastric walls and allowing a free outflow through the larger tube. When this is insufficient to detach the colonies of germs from the mucosa his gyromele comes into useful application. In cases of extreme gastric atony and dilatation, he uses the gastric bag dilator with air inflation, the repeated use of which will stir up the stomach and restore its motor function. In most cases the simple inflation of the stomach with air, medicated or not, is sufficient. Turck does not consider the use of electricity as of proved value in these cases, and he has not much faith in drugs excepting for the relief of symptoms, as in the use of alkalies for hyperacidity, etc. Antiseptics are apparently efficacious, but he considers them generally unnecessary.

The Pathological Changes in Appendicitis.—E. MacD. Stanton has studied the pathological changes in the peritoneum in 185 cases of appendicitis, and of the appendix in 188 cases. The relations existing between the character of the lesions and the stage of the disease were particularly studied in all. The histological changes in appendices removed during the first few days of the disease were essentially similar and consisted in a severe diffuse inflammation, accompanied by focal areas of hemorrhage and necrosis. These latter may increase in extent during the first few days and give rise to microscopical areas of gangrene, or they may remain microscopical and be quickly repaired. The various anatomical varieties, gangrenous, perforative, and ulcerative, are due to the extent and distribution of these necroses. Evidences of repair are seen as early as the third day and the process is distinctly reparative in non-gangrenous cases by the fifth day. Even in cases with macroscopical evidences of gangrene, unless a later acute process is engrafted on the original one, the repair processes predominate by the sixth or seventh day. Evidence of recurrence was observed in 10 or 15 per cent. of the cases after the first week. Repair is rapid during the second week of the attack; fibroblasts, newly formed blood-ves-

sels, and lymphocytes forming the principal features of the ; ire. The rapidity of repair depends largely on the amount of damage done and on the presence or absence of a periappendical exudate. By the end of the second week in most cases, repair is so complete that new connective tissue may be the only evidence of previous inflammation, but in cases with extensive exudates, signs of active organization of the exudate itself are still in evidence. After the second week, except in cases with extensive periappendical lesions, the histological changes are seen chiefly in the more fibrous nature of the new connective tissue which is still recognizable. In cases operated on a month or more after an acute attack, 78 per cent. were cases of chronic interstitial or obliterative appendicitis, frequently accompanied with adhesions. In 6 per cent. the appendices were apparently normal, and in 16 per cent. the changes were confined to the mucosa. In no instance were the changes confined to the mucosa in the cases examined during the first ten days of the attack. In this series of cases, purulent fluid was found outside of the appendix in 51 per cent. of the patients operated on from the third to the tenth days. After the tenth day the number of cases with abscesses steadily decreased while the number of those with adhesions and without pus, rose correspondingly. This, Stanton thinks, was due to the less extensive peritoneal involvement in most of these late operated cases rather than to resolution by absorption. In a number of cases, however, the massive adhesions indicated the prior existence of extensive periappendiceal exudate. After the third day the exudates on the peritoneal surface contain highly vascular granulation tissue, and he thinks it probable that the high operative mortality between the third and tenth days may be in part due to absorption from the denuded granulating surfaces as well as to the extent of the peritonitis and the bad general condition of the patients.

Expeditious Surgery.—R. T. Morris remarks that, with modern methods and anesthetics, perhaps too little importance is attributed to expedition in surgical operations nowadays, and suggests that this may be to the disadvantage of the patient. The better the natural resistance, the better is infection combated, and a patient usually retains a great fund of natural resistance during the first fifteen minutes of an operation, no matter what is being done; but he is usually depressed after an hour of operative procedure, even simple in its nature. It seems to him well, therefore, to attempt to approach as nearly as possible to the fifteen-minute standard. It is not desirable to operate against time, but it is worth while to make every move count, and not unduly to prolong the operation. He had, after a little discussion on the subject, the next dozen of his operations timed, including several rather serious ones, and reports them in brief detail, giving time and results, as illustrating his point. The time occupied by the operation ranged from seven minutes in an interval appendicitis case to thirty-one minutes in a case of preliminary ligation of the carotid and removal of the superior maxillary and other bones through the classical incision. The operative results were good. Except in two of the cases, the instruments used were usually a pair of scissors, a needle, a single-hook retractor, and two pairs of artery forceps. With the use of scissors there seemed to be less oozing of blood from the smaller ves , and fewer instruments were required. The charge that primary union may not follow the use of scissors is answered by these cases without reference to further statistics.

The Lancet, June 3, 1905.

The Second Dentition: Its Medical Aspects.—H. Armstrong declares that rickets delays the eruption not only of the milk teeth, but also of their successors, in addition to frequently causing overgrowth of the jaw, with resulting malposition. A similar retarding influence is also exerted by cretinism. It is not probable that hereditary syphilis has any effect in hastening the advent of the second teeth, though all textbooks generally assert that it has this effect on both sets of teeth. Eventually bad results as to integrity of the enamel often follow the exanthmata, bronchitis, pneumonia, and the nutritive disturbances which result from improper feeding. Alveolar abscesses in connection with the first teeth may lead to irregularities of their permanent successors. A frequent source of ill health is the incomplete detachment of the remnants of the first dentition. The teeth retain their adhesion to the alveolar mucosa long after the supplanting teeth have arrived. Food accumulates and decomposes at these points and sepsis results; the neighboring glands become swollen, though suppuration is rare. Possible outcomes are necrosis and cancrum oris. As to the influence of dentition upon concurrent general disease it may be said that the most obvious example is seen is epilepsy in which tooth eruption initiates the onset and may increase the frequency of the attacks. Hysterical conditions and chorea may also be aggravated by coincident dentition.

Typhoid Fever and Pregnancy with Special Reference to Fetal Infection.—H. T. Hicks and H. French report the case of a woman who became infected with typhoid fever at the middle of the eighth month of pregnancy. On the eighth day of the disease she was delivered of a living fetus, which died in three-quarters of an hour. The mother improved at first, but relapsed and died on the twenty-fourth day. Autopsy showed typical typhoid charges. Autopsy which had been done on the child revealed no pathological conditions. The authors have studied 30 cases of this general nature. In 10, typhoid bacilli were found in the fetal organs or blood. The typhoid agglutinin occurs in the serum of a fetus born of a typhoid mother. There is slender evidence that the typhoid reaction ever occurs in a fetus in which no bacilli have ever been found. Since it is well established that bacilli are found in the fetus, it would be reasonable to expect that the fetal tissues would produce their own agglutinins, just as occurs in an independent individual. It is barely possible that the fetus may receive the agglutinin from the mother across the placenta, or it may react to the maternal bacillary infection, producing its own agglutinins in response to stimulation by the maternal toxins. Typhoid fever occurring during pregnancy does not affect the prognosis or alter the course of the disease, but the effect of the fever on the pregnancy is bad. It is found that the uterus involutes just as if there was no maternal illness. Premature labor would seem to be indicated in the interest of the child (if viable) when the prognosis for the mother is (as experience has shown) but little affected by the occurrence of labor.

The Action of Yeast in Tuberculosis and Its Influence on the Opsonic Index.—W. R. Haggard details his personal experience with this remedy. It has been held (though not proven) that the active therapeutic factor in yeast is nuclein which increases eventually the number of the white blood cells and has a distinct bactercidal action. Haggard has treated thirty-six cases with yeast. The general result was that some improvement was noted in almost every case in which the remedy was taken steadily for at least a month. The opsonic index shows the degree to which the serum of a person's blood prepares tubercle bacilli for being taken up and digested by normal white blood cells. (See papers by Wright, *Clinical Journal*, Nov. 9, 1904, and *Lancet*, Oct. 22, 1904.) Persons recovering from tuberculosis showed an opsonic index in four or five cases above unity. Some of the lowest indices occurred in smokers. In two instances after taking yeast there was a drop in the index, but in a few days a rise above the previous level. Yeast does not appear to produce any effect on the temperature of a given case. It seems to produce an immediate and considerable increase in the number of the white cells followed by a decrease, then a fluctuation and a final diminution as compared with the level before the yeast is taken. Common German yeast has been the variety most commonly employed. A piece the size of a walnut was taken daily, usually in cold or tepid milk or in water.

Berliner klinische Wochenschrift, May 22, 1905.

Tremor as a Sign of Alcoholism.—Fürbringer discusses this question on the basis of the results obtained in the examination of 500 patients. These were divided into two groups as nondrinkers or as drinkers, the former class including moderate drinkers as well as total abstainers. The examination showed that even pronounced drunkards may not exhibit any tremor, though the proportion of such is only about a tenth, and that moderate degrees of tremor do not permit any definite conclusions as to the abuse of alcohol as there were about three times as many nondrinkers as drinkers presenting this condition. Even the highest grades of tremor do not indicate extreme probability of alcoholic excess, the number of drinkers with excessive tremor being only about twice as large as the number of non-drinkers with the same symptom. The author further says that even in marked cases, tremor of the hands has no connection with alcoholism in about one-half of the cases. Quinquad's sign, or phalangeal crepitation, apparently is subject to about the same uncertainties, so that the comparative value of these two symptoms is still to be determined.

Münchener medicinische Wochenschrift, May 23, 1905.

Loaf Sugar in Diabetes.—Oefele says that for some time he has been allowing the more intelligent of his diabetic patients to take a certain amount of loaf sugar, with very good results. In 88 per cent. of the cases it was found that after the regular consumption of 35 g. or over of sugar daily, the amount of glucose in the urine either did not increase or even decrease, while the general condition of the patients was much improved. Not only is the subjective effect on the patient excellent, but as the diabetic organism is deficient in albumins and fats, it is advantageous to have the carbohydrate metabolism increased as much as possible. A diet restricted to albumins and fats involves risk of insufficient oxidation of nitrogen and fats, with its danger of

oxybutyric acid intoxication, and the possibility of coma, and the administration of sugar does much to avoid these perils. The sugar is best given in the form of sugar water or in coffee, shortly before muscular exertion, the rule being, no sugar without exercise and no exercise without a preceding sugar feeding. The author believes that the administration of large amounts of sugar under suitable precautions, is advantageous, if not in all cases, in at least 95 per cent of diabetics. Both the actual strength and the feeling of energy are increased by this addition to the dietary.

A New Local Treatment for Furuncles and Carbuncles.—Marcus advises for this purpose the use of the electric current. If no pus formation has taken place the opening of the infected follicle is sought for with a magnifying glass, and when found, an epilating needle, forming the minus pole and carrying a current of 12 m.a. is introduced into it. The current is gradually increased up to 10 m.a. and the opening enlarged by moving the needle about so that the hydrogen generated can wash out all bits of necrotic tissue, pus, etc. The needle is then removed and reintroduced after reversal of the current, so that the oxygen which is now generated shall thoroughly disinfect the follicle, after which a final cleansing of the cavity is carried out by means of another minus treatment. Every suspicious follicle is treated in this way and the development of true furuncles is aborted. If pus has already formed the cavity is explored with a larger needle until the entire necrotic plug has been broken up and expelled by the nascent hydrogen. As long as suppuration keeps up the procedure must be repeated twice a day. Wet dressings of plain water are applied, and it is surprising to see even large furuncles clear up under five or six days of this treatment. Of course, if there is extensive swelling or phlegmonous inflammation, incisions must be made as usual.

Deutsche medizinische Wochenschrift, May 25, 1905.

How Is the Position of the Apex Beat of the Heart to Be Determined.—Kirchner says that he has frequently been called upon to examine persons supposed to be suffering from some cardiac disease because the apex beat had been found externally to the mammary line, whereas there was absolutely no evidence of any organic derangement. In these cases it is nearly always the nipple which is at fault, owing to abnormalities of its position, and the author cites his own results obtained by examining 900 soldiers. Very marked variations in the position of the nipple were found, the limits lying between 9 and 13 cm. from the middle line. It was also found that the apex beat in many instances was outside the nipple line, in a few cases as much as two to two and a half centimeters, while it was at the nipple line in only about half the total number of cases examined. The author therefore strongly urges that the mammary line be not used as a landmark in denoting cardiac dimensions, and that all measurements be made from the median line of the body.

Neurasthenia Among the Working Classes.—Leubuscher and Bibrowicz give the results of an interesting study of neurasthenia as found among 1,564 patients belonging to the various mechanical trades. Almost one-third of the patients were either compositors, carpenters, locksmiths, or mechanics, the others belonging to such a diversity of trades that definite percentages could not be calculated. The typesetters and carpenters together comprized 25 per cent. of the total number, the former workers being apparently the most prone of all to neurasthenic disorders. The authors believe that neurasthenia is rapidly growing in prevalence among the working classes, and that it is the workmen of the better types who are the most susceptible to it, owing to the spirit of unrest and dissatisfaction that prevails among them. The disease is most serious as an obtacle to work during the ages from twenty-five to forty-five years, that is the period of greatest activity. The prophylexis of course involves very far reaching questions of sociology and the treatment is best carried out in suitable institutions. Sanatorium treatment offers the greatest prospects of a permanent cure as well as of immediate relief to the symptoms, and therefore the erection of such establishments for the masses is strongly to be urged.

French and Italian Journals.

Recovery in a Case of Addison's Disease.—Variot states that Addison's disease scarcely ever appears in children, only at the age of puberty. As is well known, the disease is due to the tuberculosis of the suprarenal capsules. The affection as a rule is very grave. However, in some cases, treatment will triumph. The writer cites the case of a young man twenty-one years old who had suffered with this malady for eight years. When seen by Variot, he had the characteristic weakness, being fatigued by the least effort. The skin of the face, hands, and back was pigmented. For several years the patient had taken suprarenal capsules in the form of tablets and subcutaneous injections. The medication had apparently met with no results. To this was added codliver-oil and arsenic. Little by little, strength returned, and the extreme pigmentation disappeared. To-day there remain of the old symptoms only incontinence of urine and a slight weakness. The writer is of the opinion that gradual recovery will take place.—*Journal des Praticiens,* May 20, 1905.

Atrophic Cirrhosis of the Liver of Tuberculous Origin.—Boinet and Vincentelli have studied this case. The cirrhosis of the liver, according to these authorities, is not due to alcoholism, but is attributed to tuberculosis. The patient was a girl eighteen years old, suffering from tuberculosis in the last stages. Dyspnœa was intense. Tuberculous peritonitis with ascites was present. Severe epistaxis occurred and the patient complained of anuria. The whole condition was bad. Death supervened after a period of coma. At autopsy the liver presented an interesting appearance. It was small, hard, and it creaked under the knife. It was about one-third its normal size. In color it was yellow. It had the "hobnail" characteristics. In appearance it was an example of the classical acohol atrophic cirrhosis. But since alcoholism did not exist, the lesions had to be attributed to tuberculosis. Macroscopically, there were no tubercles to be seen. However, Hanot and Gilbert have demonstrated experimentally that Koch's bacillus can, by means of its toxins, determine hepatic sclerosis, without the production of tubercles in that organ.—*La Médecine Moderne,* May 17, 1905.

Diabetes of Infectious Origin.—Marcel Labbé cites two observations in which diabetes followed an infection. In the first instance, the patient was a man aged forty-five years, obese, and who exhibited after an attack of angina severe diabetic symptoms: Intense thirst, extreme fatigue, progressive diminution of sight, emaciation, polyuria and glycosuria. Treatment was begun at once and the symptoms began to subside in four days. After a month and a half they had completely disappeared. For two years there has been no glycosuria. The second patient was a woman sixty-seven years old, who in her convalescence from an acute naso-pharyngeal attack, showed about the same symptoms as were enumerated in the last case. They gradually disappeared. The writer refers here to the condition of alimentary glycosuria noted in the course of various infectious diseases. It would seeem from these observations that infection is capable of causing a disturbance in the organism which gives rise to the condition of glycosuria. As a rule, these disturbances are slight, giving rise to alimentary glycosuria only, but in certain cases they are more serious, and actual diabetes develops.—*Le Bulletin Médical,* May 20, 1905.

Potomania in a Child.—Achard and L. Ramond have been observing a child seven years old and weighing 15 kilogrammes, who drank from seven to eight liters of water a day, and urinated in the same proportion. The urine shows no other anomaly than great dilution. The clinical picture was that of essential polyuria. A number of these cases have been noted in children. The pathogeny of these cases has been widely discussed, but modern authorities consider the polydipsia as a simple effect of the polyuria exclusively due to the necessity of combatting the tendency to dehydration. The child here mentioned was put on a fixed regime and was able to drink a litre and a half of water daily without any trouble. Diuresis diminished in proportion and the weight was not decreased. It is clear that the child drank the original quantity not to satisfy an organic necessity as in true polyuria, nor was it influenced by the desire to drink a liquid having a certain taste as in dipsomania, but it merely acted in obedience to a psychic impulse by which it took any sort of liquid. The case is then an example of true mania for drinking, which is designated by the term potomania.—*Gazette des Hôpitaux Civils et Militaires,* May 16, 1905.

A Case of Barlow's Disease.—Filippo Pagliari reports a case of Barlow's disease in an infant which was breast fed for forty days and then began to take sterilized milk. At the age of eight months, she presented a pitiable spectacle. There was persistent and progressive anemia, general depression, wasting, cachexia, and an inability to use the limbs, any movement of which caused the utmost pain. There were present only the two upper incisors, and the gums about them, as well as of the lower jaw were swollen, purple, and hemorrhagic. There was a copious pemphigoid eruption over breast, shoulders and neck. After changing the diet to plain milk with fruit juice the infant began to improve and eventually entirely recovered. The author duscusses the case and concludes that this disease is a definite entity, and an addition to the number of hemorrhagic diseases. It may be called a scorbutic syndrome of nurslings. It is probably an infectious disease, in which the kind of feeding may be a contributing cause of the disease. Sterilized milk is deprived of the natural antagonistic substances and hence the child is ready to accept the infection. Very few cases of this disease have been observed in Italy up to the present time, but probably because they have not been

diagnosed as such, but have gone under some other name.—*Rivista di Clinica Pediatrica*, May, 1905.

Experimental Infection with the Micrococcus Tetragonus Septicus.—Errico Claramelli tells us that the experiments that have been made since the discovery of the micrococcus tetragonus have shown it to be very pathogenic for some animals, and not so for others, such as the rabbit. The author has made experiments to demonstrate this and gives us his conclusions. The micrococcus in sufficient doses produces a mortal infection in guinea pigs. In smaller doses the animal is poisoned but recovers. The rabbit is very resistent even to large doses given endovenously. There are the symptoms of a grave infection of which the animal gradually recovers. The blood contains the bacteria constantly in considerable quantities. The characters of the bacteria are those of involution, but the power of reproduction is preserved. The serum of the cured animal has the power of sterilizing the micrococcus tetragonus with the mechanism of bacteriolysis, if injected into another animal. —*La Riforma Medica*, May, 1905.

Cystic Hemoangiosarcoma of the Kidney.—Allessandro Jardini describes his study of a case of cystic tumor of the kidney, which he diagnoses as hemoendoangiosarcoma. The classification of endothelial tumors depends on the definition of the term endothelium. Some admit among endothelium only the elements which line the blood-vessels and lymphatics, others include the lining of the great serous cavities. Another point equally discussed regards the existence of a sheath of the vessels constituted of elements of an epithelial nature. Histogenetically these tumors are divided into hemoangiosarcomata and lymph angiosarcomata. The case observed was that of a patient dying in the hospital of a trouble diagnosed as cardiac insufficiency, having been under observation only a few days. The tumor of the kidney was found at the autopsy without any symptoms during life that indicated its presence. The diagnosis clinically between angiosarcoma and any other tumor of the kidney would be difficult, even were the presence of a tumor recognized. The right kidney was double the normal size and the superior pole was formed of a mass continuous with the parenchyma of the kidney, which was full of small cavities, varying in size, filled with coagulated blood of the color of coffee. The size of the cavities varied from that of a grain of millet to that of a small nut. The rest of the tissue was white in color, glistening, and the larger cavities were at the centre, the smaller at the periphery. These cavjties could not be interpreted as hemorrhages, but were evidently the result of a form of activity inherent on the kind of neoplasm found here. There was no inflammatory reaction of the surrounding tissues as in carcinoma and infiltrating tumors.—*Lo Sperimentale*, March-April, 1905.

Annals of Surgery, May, 1905.

Actinomycosis.—A. D. Bevan gives a general description of this malady and reports six personal cases. With reference to the microscopical findings he says that later investigations have taught us not to expect to find the beautiful and clear radiating clubs pictured, especially from cases of bovine actinomycosis. Instead of this, the picture is rather blurred; often the organisms have undergone some degenerative process, which leaves nothing distinctive, and it may be necessary to search for a very considerable period before a sufficiently characteristic body is formed. He is rather led to believe that the fact just cited, *i. e.*, the difficulty of finding a clear, distinct picture of the fungus under the microscope, has frequently been the cause of error in diagnosis, and responsible for failures to recognize the lesion, when, in fact, it was present and typical. As an instance, he refers to the fact that an exceptionally well qualified diagnostician was given some pus from one of our cases, a case of lung actinomycosis. There were present many of the granules. After working over it for two hours, he reported that it was not actinomycosis, as far as he could determine, although both before and after the examination we found typical ray fungi in the pus from the same source.

Transthoracic Resection of the Lower End of the Esophagus in a Dog.—Willy Meyer gives an interesting account of a resection of the nature indicated, performed by Sauerbruch of Breslau. He refers to the article by the latter in which this author describes his investigations into the general subject of how to best prevent the occurrence of a pneumothorax in inthrathoracic surgery, the main point to be considered being to render practicable transpleural resections of the esophagus. An illustrated description is given of the apparatus employed. It is evident that operotions of the nature referred to must be done either by increasing the pressure within the lungs, exposing the thoracic cavity at the same time to ordinary atmospheric pressure or by placing the thoracic cavity under decreased or negative pressure while the bronchial system remains exposed to normal atmospheric pressure. Various experiments on dogs are described in full. The general physiological proposition demonstrated by Sauerbruch's work is that rhythmical, artificial charging of the lungs with air, corresponding to normal respiration—as has been long done by physiologists—is not necessary to continue respiration with the thoracic cavity opened, but that spontaneous respiration goes on regularly and uninterruptedly, if a pressure difference is maintained between the air entering the bronchial tree and that to which the pleural cavity is exposed. This normal respiration goes on uninterruptedly, it may be added, even if the greater part of the thoracic wall is resected.

Resection of the Middle Third of the Stomach for Carcinoma of the Greater Curvature.—C. L. Scudder reports one case, his patient being a woman of thirty-seven years who is alive and well ten months after operation. The case is of interest because (1) carcinoma of the greater curvature of the stomach is unusual. According to Fenwick, 58 per cent. of all gastric carcinomata are pyloric. Upon the contrary, but 2.8 per cent. are of the greater curvature. (2) The growth did not infiltrate the submucosa as is commonly the case with plyoric carcinoma. (3) The growth had attained considerable size without causing many symptoms of gastric disturbance, for neither the pyloric nor the cardiac portions of the stomach were invaded. (4) The transverse colon was not involved in the disease. (5) An end-to-end anastomosis was done, using an interrupted Connell suture. (6) The technique of the operation was very greatly facilitated by the employment of clamps according to the methods of Kocher, Hartmann, Mayo, and Moynihan. Some excellent pictures illustrate the successive steps of the operation.

Hydrocele in the Female.—A. E. Halstead and C. P. Clark review the literature of this disease and report one case, that of a colored woman, married, aged forty-two years. The condition for which she sought relief was a mass in the right inguinal region. It appeared eighteen years ago, subsequent to the birth of the second child. The patient stated that the mass had always been reducible, but that it would reappear in four or five days after reduction. Eight days previous to admission the mass would no longer disappear on pressure. The patient now became slightly constipated and nauseated. She had emesis twice. There were severe pain and marked tenderness in the region of the mass. The diagnosis was strangulated hernia. Operation revealed the fact that the condition was one of hydrocele. The mass removed was made up of a bilocular cyst, the dividing plane being the internal addominal ring. The upper sac lay entirely within the peritoneal cavity. The round ligament entered this sac and became attached to its inner smooth surface. At the point of entrance was a small opening which allowed a free communication between the cyst and the peritoneal cavity. The lower sac was much larger than the upper, and contained many incomplete septa, giving the appearance of a lymphangioma cysticum. The lower and upper sacs communicated through a narrow constriction at the internal abdominal ring. Near this constriction was found a bean-shaped body which lay free in the lower sac. The latter proved to be made up for the most part of fibrous tissue which had apparently been the seat of a recent inflammatory process. The presence of vessels in it indicated that it had been at one time attached to the wall of the hydrocele.

Tuberculosis of the Testis.—J. S. Haynes reports one case. He finds that the predisposing factors are: Age, about thirty when the glands are most active, hereditary, trauma (which, whether slight or severe, probably plays a very prominent part in locating the disease in the epididymis by the normal arrangement of the blood supply), and previous gonorrhea. The local changes are those characteristic of tuberculosis elsewhere. Local symptoms are those of weight and discomfort with dysuria. The urine rarely gives positive evidence of the disease. The smegma bacillus may be easily mistaken for the tubercle bacillus. Sexual vigor is generally unimpaired. General symptoms are those of the lesion elsewhere. The author reviews the results obtained by the various plans of treatment, viz., castration, avulsion, ligature, and resection, incision and drainage. He believes that statistics incline to epididymectomy as the preferable procedure.

Rupture of the Tendon of the Biceps Flexor Cubiti.—W. W. Keen reports a case of rupture of the long tendon in its continuity and one of rupture of the same tendon at the glenoid attachment. In each case a successful result followed operation. He notes that surgical literature hitherto contains records of only one case of operation for rupture of the belly of the biceps and one for rupture of the tendon. Many cases of the accident itself are on record. Keen is of the opinion that the general success attending operation, and the poor results in many cases not so treated, should lead to operative treatment of cases of rupture rather than to trust to the more or less uncertain results of the treatment by bandages and splints.

Book Reviews.

Conservative Gynecology and Electrotherapeutics. A Treatise on the Diseases of Women and Their Treatment by Electricity. By G. Betton Massey, M.D., Attending Surgeon to the American Oncologic Hospital, Philadelphia; Fellow and ex-President of the American Electrotherapeutic Association; Member of the Société Française d'Électrothérapie, of the American Medical Association, etc. Fourth Edition, revised, rewritten, and greatly enlarged. Illustrated with twelve original full-page, chromo-lithographic plates and twelve full-page half-tone plates of photographs taken from Nature, and numerous engravings in the text. Philadelphia: F. A. Davis Company, 1905.

Since the last edition of this book appeared great progress has been made in electrotherapeutics; hence we find much new material in this edition, notably in the sections dealing with the constant current, electrolysis, and cataphoresis. There are also four new chapters on the treatment of cancer by electricity, and a chapter on the Röntgen rays in diagnosis and treatment by Dr. Grad of New York. The book still remains, as its title indicates, a work on conservative gynecology; and as such it will be of service to the many physicians who believe that the surgical is not the only method of treatment in gynecology, and who are willing to try therapeutic measures before resorting to mutilating operations. The author eloquently pleads for a trial of electrotherapeutics, and gives in considerable detail the results of such treatment in his hands. The author's position is well stated when he says: "No claims that electricity, or, in fact, anything else, is a cure-all are possible to a scientific mind, and, although these pages are largely devoted to a demonstration of its value in the definite conditions enumerated, it is not supposed that the reader is to neglect any simpler means that would be effective in the treatment of his cases. . . . A similar discretion is also urged upon the part of the reader in the choice between electricity and the knife, electricity being advised only when it is equally certain in effect, free from danger, and more conservative of organs and their functions; and, unless experience shows us that all or most of these advantages are assured as a result of the electric treatment of a particular case, we should not lose time by its employment."

The Conjunctiva in Health and Disease. Being a Record of Some Research Work. By N. Bishop Harman, M.A., M.B. Cantab., F.R.S.C. Eng., Ophthalmic Surgeon to the Belgrave Hospital for Children; Chief Clinical Assistant, The London Royal Ophthalmic Hospital (Moorfields); Senior Ophthalmic Assistant, The Middlesex Hospital; Oculist (with Care of Blind Children), London County Council Schools; Demonstrator of Pathology, Middlesex Hospital Medical School; Late Examiner, Natural Sciences Tripos, Cambridge University. New York: William Wood & Company, 1905.

The volume is one of 276 pages, is well printed, and is illustrated by 43 original drawings. The work is the result of a very careful study of the subject in all of its phases, many thousands of eyes in health and disease having been examined. In addition to the very extensive clinical work, the author has familiarized himself with the pathology of the subject, also with the literature not only of this but of previous ages.

The text is divided into twenty chapters. Chapter I, entitled "Historical," gives some interesting extracts from old writings. Then follows a chapter on "The General Anatomy of the Conjunctiva." This is followed by a chapter entitled "Sociological Inquiry," which treats of the influence of sex, age, environment, seasons, etc. The results of the author's studies into these questions are of much interest. A chapter is devoted to the consideration of "The Causes of Blindness." The bacteriology of the conjunctiva in health and disease is then taken up, and the various forms of conjunctivitis are considered in logical order in separate chapters. The question of trachoma, which involves so-called follicular conjunctivitis, is treated of in such a manner that our knowledge of the subject is materially advanced.

The text is followed by an extensive bibliography, so subdivided that it can be readily utilized by the student.

The data that the author has employed in writing the work have been secured at the expense of an immense amount of personal observation and research. The result is a volume of great excellence and one that should be in the hands of every ophthalmologist.

Merck's Manual of the Materia Medica. A Ready-Reference Pocket Book for the Physician and Surgeon. New York: Merck & Co., 1905.

This edition of Merck's Manual, like its predecessors, contains much useful information in regard to the drugs most used in modern practice, as well as dosage tables, the treatment of poisoning, therapeutic indications, etc.

Wharton and Stille's Medical Jurisprudence. Vol. III, Physical Conditions and Treatment. Medical Aspects. By Truman Abbe, A.B. (Harv.), M.D. (Col.), Assistant to the Professor of Surgery and to the Professor of Physiology at the Georgetown University Medical School. Legal Aspects, By Frank H. Bowlby of the Publishers' Editorial Staff. Fifth Edition. Rochester, N. Y.: The Lawyers' Co-operative Publishing Company, 1905.

This volume of Wharton and Stillé's system is devoted to a widely varying range of subjects. The first book comprises questions relative to pregnancy, abortion, and infanticide; the second is devoted to questions arising out of the difference of sex, including hermaphroditism, sexual disability, and rape. Physical injuries by force are discussed in the third book, which also contains sections on starvation and the signs of death. The largest section of the volume is the fourth book, in which questions distinctively legal in nature are taken up. Among these are such vital topics as the right to practise medicine, the relation between physician and patient, malpractice, and medical evidence. The first three books have been almost entirely rewritten in order to keep them representative of the present status of scientific knowledge, and are fully abreast of the times. Much new matter is also to be found in the last section, which covers subjects in which every physician, for his own protection if for no other reason, should be well versed. The subjects treated by the work are numerous, but the writers have been most successful in their apportionment of space to the different topics and have produced an extremely useful work of reference.

Studies in the Psychology of Sex. Sexual selection in man. I. Touch; II. Smell; III. Hearing; IV. Vision. By Havelock Ellis. Philadelphia: F. A. Davis Company, 1905.

The task attempted in the present volume is an analysis of the psychology of love, or sexual selection. Love, the author states, springs up as a response to a number of stimuli transmitted through the four senses, touch, smell, hearing, and vision, and by this process the organism is brought into a physical and psychic state of tumescence necessary to insure conjugation. In other words, when a man or woman experiences sexual love he or she is responding to a group of stimuli coming through the channels of one or more of these senses, entirely independent of any esthetic preferences, which need not be consciously present at all; there has been a sexual selection conditioned by sensory stimuli. This in brief is the doctrine of sexual selection established, so the author affirms, on a sound basis, to a consideration of which the reader's attention is invited in chapters entitled Touch, Smell, Hearing, and Vision. These are comprehensive recitals of the effects of skin sensations, odors, rhythm, beauty, and color on the human organism, and the part they have played in influencing sexual selection.

To those familiar with this author's work in other fields of psychological research, this volume should especially appeal. As he truthfully says, such a study is full of fascination, for it reveals to us the more intimate side of human evolution whereby man is moulded into the shapes we know.

Le Beriberi; Définition, Etymologie, Historique, Bacteriologie, Symptomatologie, Pathogénie, Pathologie expérimentale, Traitement. Par le Docteur H. Vivian Dangerfield. Paris: A. Maloine, 1905.

This is a monograph on beriberi, containing 450 pages and representing seven years' continuous work on the part of the author. It is, in all probability, not only the most recent, but also the most complete work on the subject. The book is divided into two parts, of about equal length; the first consisting of the etiology, bacteriology, symptoms, diagnosis, pathology, treatment, etc.; while the latter half contains the histories of 151 cases under observation during the past seven years. The value of the work is enhanced by an historical sketch containing a list (with dates) of almost every writer who has referred to the disease. There is also a good modern bibliography. The cause of beriberi, which the author admits is unsettled, he is inclined to attribute to a coccus which he calls *Micrococcus beribericus*.

Veröffentlichungen aus dem Gebiete des Militär Sanitätswesen. Heft No. 28. Beiträge zur Schutzimpfung gegen Typhus. Berlin: Aug. Hirschwald, 1905.

This brochure contains the results of an investigation instituted by the Medical Department of the Prussian War Office and carried out by a number of staff officers both in Germany and the Colonies. As regards the universal application of preventive inoculation in the army, is appears that the results thus far obtained do not warrant the procedure being made compulsory. Even where it has been carried out, the usual sanitary prophylactic measures should not be omitted. The report is quite exhaustive and forms a valuable contribution to the literature of the subject.

Society Reports.

AMERICAN GASTROENTEROLOGICAL ASSOCIATION.

Eighth Annual Meeting, New York, April 24 and 25, 1905.

(Special report to the MEDICAL RECORD.)

FIRST DAY, MONDAY, APRIL 24.

THE PRESIDENT, DR. S. J. MELTZER OF NEW YORK, IN THE CHAIR.

The President's Address.—Dr. S. J. MELTZER, in his opening address, confined himself largely to a brief biographical sketch of three deceased foreign members of the Association, namely, Franz Riegel, Samuel Fenwick, and Adolf Kussmaul.

Recent Advances in the Knowledge of the Movements and Innervation of the Alimentary Canal.—Dr. WALTER B. CANNON of Boston, Mass., read this paper in which he said that undoubtedly the most important factor of the newer physiology of the mechanism of the stomach was the knowledge that it consisted of two parts, physiologically distinct. The larger, left part of the stomach was the cardiac portion; the right, the pyloric portion. The latter was characterized during digestion by the continuous passage of peristaltic waves over its surface, to the pylorus. The cardiac portion was without peristalsis, but as the food was pressed from the pyloric portion into the intestine, the muscles of the fundus, by tonic contraction, squeezed the contents into the mort active division, as into a hopper. The rate of gastric peristalsis varied with different animals. Roux and Balthazard stated that in the human being the rate was about three per minute, and Dr. Cannon said he had been able to confirm this statement by means of auscultation. Different views had been set forth as to the manner in which the pylorus opened and permitted the exit of food. Some investigators had declared that the sphincter relaxed only at the end of several hours to allow the stomach to empty. Observations with the stomach tube and *x*-rays showed that the stomach was not emptied at once at the end of gastric digestion, but progressively during the period. There was, then, an intermittent closure of the pylorus. The channel was usually closed, yet occasionally it opened; and when it opened, the peristaltic wave usually engaged in churning the food now served to propel it into the intestine. It seemed probable that the signal for relaxation was the presence of free hydrochloric acid on the stomach side of the pylorus.

Dr. MAX EINHORN of New York thought there were other factors that played a part in the relaxation of the sphincter besides the presence of free hydrochloric acid on the stomach side of the pylorus. This theory was satisfactory under normal physiological conditions, but it would not explain the relaxation of the sphincter in cases, for example, of achylia gastrica, where there was no acid in the stomach, and still the food found an exit into the intestines.

Dr. A. L. BENEDICT of Buffalo said that in dealing with stomach troubles, so many curious combinations were encountered that the matter of therapeutics was often very puzzling, and every strictly scientific paper, like that presented by Dr. Cannon, might help in the practical solution of the problems that had to be dealt with.

Dr. Cannon, in closing, said he agreed with Dr. Einhorn that the influences governing the action of the pylorus were still vague, and the problem had to be solved from a physiological standpoint before it could be intelligently attacked under pathological conditions.

Recent Advances in the Knowledge of the Chemical Processes of Digestion.—Dr. LAFAYETTE B. MENDEL of New Haven, Conn., in this communication, stated that perhaps the most striking factor of the present development of the study of digestion was the increasing complexity with which the explanation of this function was attended. From whatever standpoint the chemical processes were reviewed, the enzymes or simple ferments took the most important place among the active agents involved. The question as to their exact chemical nature was still unsolved, but with the increasing attempts to interpret physiological reactions in the light of modern physiological chemistry, instead of the more obscure "vitalistic" conceptions, there was a growing tendency to regard enzymes as special types of catalytic agents, colloidal in nature, which were subject to the general laws applicable to the inorganic catalyzers. The so-called reversible action of enzymes deserved special notice, since it threw new light upon the synthetic process in the organism. The researches of recent years had taught us that enzymes cooperated in the alimentary digestive process under conditions which had heretofore not been appreciated, and we had learned to recognize the existence of entirely new types of soluble ferments.

The F. A. Hoffmann-Ostwald Method of Determining the Free Hydrochloric Acid of Gastric Juice by Dissociation of Methyl Acetate.—Dr. JOHN C. HEMMETER of Baltimore illustrated this method and presented a brief paper on the subject.

The Immediate Effect of Biliary Retention on the Gastric Secretion.—Dr. JULIUS FRIEDENWALD of Baltimore sent this paper which was read by Dr. H. W. Bettmann. The author stated that the fact that one digestive secretion exerted a marked influence upon another secretion had been well known for a long time. It was a well-known fact that all forms of intoxication of the system could markedly influence the gastric secretion, and change its character. The cholemic condition due to biliary retention was much like the uremic condition due to ligation of the ureter, in which marked disturbances of the gastric secretion were known to take place. The first really systematic examination in this regard was made by Simnitzky. He investigated, especially, cases of catarrhal jaundice, because in that disease the jaundice gradually increased and then gradually again diminished. Beginning the examinations early, and continuing them as the jaundice intensified and as it again diminished, the direct effect of the jaundice upon the gastric secretion could be observed. As a result of careful investigation he found that in those cases in which there was at first a complete biliary retention which gradually began to clear up, the total acidity, as well as the percentage of free hydrochloric acid gradually diminished, and that with the retention of the bile, the gastric acidity increased in proportion to the degree of the biliary retention, the increase in acidity being due mainly to free hydrochloric acid.

Dr. EINHORN said he had certainly seen cases of jaundice and hypertrophic cirrhosis of the liver in which there was no evidence of an increase of hydrochloric acid, but rather a diminution. In the majority of cases, the observation contained in Dr. Friedenwald's paper might be correct, but it could not be accepted as a general rule.

Are the Milk Coagulating and the Proteolytic Effects of the Gastric Juice Due to One and the Same or to Two Different Enzymes?—Dr. JOHN C. HEMMETER of Baltimore read a paper with this title, in which he discussed the various theories that had been advanced on the subject.

Diverticula of the Esophagus, with Report of Three Cases.—Dr. WILLIAM GERRY MORGAN of Washington, D. C., presented a paper on this subject which was read by Dr. John P. Sawyer. He stated that ectasies or enlargements of the esophagus were of two kinds, entirely distinct in their causation and pathology, namely, dilatations, or diffuse enlargements involving more or less the entire periphery of the tube, and due usually to organic or spasmodic stenosis; and diverticula consisting of localized bulgings or saccular protrusions, and originating from a circumscribed portion of the wall of the esophagus. Pressure diverticula were those produced by the intraesophageal pressure involved in swallowing, acting upon a circumscribed area of weakened esophageal wall. They were uncommon, and occurred much less frequently than traction diverticula. They might be single or double. They were rounded or oval saccular protrusions, communicating by a circumscribed or

slit-like opening with the lumen of the esophagus. The esophageal diverticula that gave rise to perceptible clinical symptoms and came under observation and treatment were practically all of the pressure variety. With regard to location, while pressure diverticula might occur in any part of the esophagus, they were divisible into two well-marked classes, (1) those at the junction of the pharynx and esophagus; (2) those below the cricoid cartilage. Traction diverticula were pouches or eversions produced by traction from without, or cicatrices or bands adherent to the esophageal wall. They were the commonest form of esophageal diverticula, occurring, it was said, in from one and a half to four per cent. of all adults. They were nearly always situated in the middle of the esophagus, in the vicinity of the bifurcation of the trachea, with some preference for the right side. The great majority of them resulted as a sequela from tuberculous anthracic or other form of inflammation of the bronchial glands situated at the bifurcation of the trachea. On account of their small size, traction diverticula produced no manifest symptoms, and rarely, if ever, had they been diagnosticated or even suspected during life. The initial symptoms observed in the upper diverticula, aside from whatever history there might be of the lodgment of foreign bodies, etc., were those of irritation, expectoration of mucus, irritable cough, hawking, or of slight difficulty in swallowing. In the low situated diverticula the earliest symptoms were usually a sense of dull, vague pressure, and slight pain or burning during the act of swallowing. In cases where the power of swallowing was greatly impaired or entirely abolished, a gastro-enterostomy and feeding through the fistula afforded one method of keeping up the patient's nutrition. When the dysphagia was extreme, and the esophagus passable by the stomach tube, a far better way of feeding was by gavage, which the patient could learn to perform for himself.

A Case of Fatal Hemorrhage from the Upper Gastro-Intestinal Tract, Without any Gross Anatomical Lesion.—Dr. I. Adler of New York reported this case in detail, and exhibited the specimen.

Further Remarks on Ischochymia and Its Treatment.—Dr. Max Einhorn of New York City read this paper. Ischochymia, he said, or the "clinical dilatation of the stomach" of the older writers, was an important disease, to the recognition and treatment of which modern stomach pathology had made many contributions. As to the frequency of the condition, Dr. Einhorn said he met with 47 cases of ischochymia, of benign or malignant nature, among 3,243 cases of stomach disorder. It was generally well known that cases of benign ischochymia which were caused by a moderate stenosis of the pylorus might be improved or cured by medical treatment. In these cases, dilatation of the stomach was not very great, and the peristaltic restlessness of the organ was absent or only slightly present. There were, however, exceptional cases of tremendous gastric dilatation, filling the entire left side of the abdomen down to the symphysis, with marked peristaltic restlessness, which might be cured by palliative treatment. Usually, cases of benign ischochymia gave a long history of suffering, with periods of interspersed euphoria, whereas cases of malignant ischochymia gave a short history of illness, (3 to 8 months), with constant suffering. There were, however, exceptions to this rule. Benign ischochymia required, first, medical treatment. If this proved unsuccessful, *i.e.* if after a prolonged period of treatment the fasting stomach on a fluid diet was not emptied, but contained food remnants, an operation was advisable. Second, surgical intervention was also indicated in benign ischochymia which had developed subsequent to a condition of continued hypersecretion of gastric juice, preceded by hemorrhage or not. Third, malignant ischochymia was one of dubious nature, in which, however, a thickening of the pylorus was found. It should be treated surgically.

Dr. A. Rose of New York said the name ischochymia used by Dr. Einhorn in his paper was misleading. *Ischo* meant to check or arrest something by a force which was actively applied. The term, therefore, was not appropriate in a case where there was passive obstruction, like stenosis or atony. Dr. Einhorn had taken the word from ischuria, where the retention of the urine was caused by a spasm of the circular or longitudinal fibers, but the word ischuria would not be appropriate when the retention of the urine was due to paralysis of the detrusor vesicæ.

Dr. W. H. Bettmann of Cincinnati said he thought it very important that the profession should know that cases of ischochymia, with obstruction at the pylorus, recovered under medical treatment. The surgeons were too apt to overlook that fact, and to recommend surgical interference rather recklessly in some cases. The obstruction might be either (1) an actual anatomical one; (2) a spasmodic obstruction; (3) due to muscular weakness. If the obstruction was an anatomical one, it could not be removed by medical treatment, but this did not apply to the other two types.

Sarcoma of the Stomach, with the Report of Two Cases.—Dr. Morris Manges of New York, read this paper, and presented the following conclusions: (1) Sarcoma of the stomach usually occurred before 35 years of age, so that the younger the patient, the greater the probability that the malignant affection was sacromatous in character. (2) In many cases there was slight but continued pyrexia, accompanied by rapid and profound anemia, while in carcinoma fever was usually absent during the early stages of the complaint, and the cachexia much more gradual in its development. (3) Enlargement of the spleen was by no means infrequent, but it was rarely met with in cancer unless the organ was involved in the growth. (4) According to Kundrat, the tonsils were apt to enlarge, and the follicles upon the sides of the tongue might become swollen or ulcerated. (5) Secondary deposits in the skin occurred in a notable proportion of the cases that permitted of excision and microscopic examinations. It should be remembered, however, that sarcomatosis had been met with in true cancers of the stomach (Leube). (6) A large nodular tumor due to infiltration of the omentum, and greatly enlarged liver, with secondary growths in its substance, was rarely met with. (7) The discovery of pieces of morbid growth in the vomit rendered its diagnosis certain (Riegel; Westphalen). When the diagnosis was made, arsenic should be used, as it was in other cases of lymphosarcomatosis. Otherwise, the treatment was strictly surgical.

On the Relations of Some of the Metabolic Diseases to Intestinal Disorders.—Dr. T. B. Futcher of Baltimore stated that some of the more obscure and rare metabolic diseases had been attributed by investigators to disturbances in intestinal function; among these he mentioned alkaptonuria, ochronosis and cystinuria. Alkaptonuria was first described by Boedeker in 1859. The characteristics of the urine in this condition were briefly as follows: When voided it had a normal appearance, but rapidly acquired a deep-brown color and ultimately became black on exposure to the air. It was not until 1891 that Baumann and Wolkow demonstrated that the peculiar reactions of alkapton uric urine were due to the presence of homogentisic acid. The view generally held regarding the etiology of alkaptonuria was that the conversion of tyrosin into homogentisic acid was due to bacterial activity and consequent putrefactive conditions in the upper intestinal tract. The condition was congenital in the vast majority, if not all of the cases. Dr. Futcher said that recent observations indicated that a pathologic condition of great interest and rarity was associated with and probably due to the metabolic disturbances in alkaptonuria. This was the remarkable affection known as "ochronosis," or pigmentation of the cartilages, first described by Virchow in 1866. Osler, a year ago, reported two cases of ochronosis in alkaptonuric brothers, both of which cases had been previously reported in the literature as alkaptonurics, one by Marshall, and the other by Dr. Futcher. These constituted two of the four instances of alkaptonuria in this country.

Another metabolic disturbance which had generally been regarded as being dependent on intestinal disturbance was cystinuria, characterized usually by the spontaneous deposition of hexagonal cystals in the urine. The clinical significance of cystinuria was not great, because it was commonly associated with definite symptoms, and might be well developed in persons in good health. Occasionally, the individuals had disordered digestion, or it might be associated with anemia. Cystinuria was at times of surgical importance, owing to the fact that renal calculi composed of cystin might occur. Regarding its cause, the view was generally held that it was closely related to putrefactive changes in the intestinal tract.

Dr. JOHN P. SAWYER of Cleveland spoke of the relief in diabetes that followed the use of stomach lavage, especially when the condition was associated with hyperchlorhydria.

Dr. EINHORN said he had also observed quite a number of cases of diabetes associated with hyperchlorhydria in which the use of alkalies reduced the quantity of sugar in the urine.

Occult Blood in the Feces and Its Clinical Significance.—Dr. J. DUTTON STEELE of Philadelphia said that during the past few years, considerable attention had been paid to the clinical importance of recognizing minute quantities of blood in the discharges of the gastrointestinal tract. The term "occult blood" had been given to these hemorrhages, since the amount present was always too small to give the usual macroscopic characteristics of blood in the feces or gastric contents. Moreover, by the time the blood had passed from the body, the corpuscles were so broken down that they could not be recognized with the microscope, and the traces of blood had to be detected chemically. The tests that had been found most suitable for clinical use was the guaiac test of Weber, and the aloin test, first suggested by Klunge and Schaer. In Dr. Steele's experience, the latter had been found the more reliable, although the guaiac reaction was very satisfactory. A series of observations upon two normal subjects had convinced him that red meats, if taken in sufficient quantities, would give a very decided reaction for blood in the feces. The writer then discussed the value of the test in gastric and duodenal ulcer, in carcinoma of the gastrointestinal tract, in cirrhosis of the liver, in purpura, in tubercular enterocolitis and in typhoid fever. In the latter disease its application had been disappointing, although his observations had not gone far enough to be conclusive.

SECOND DAY, TUESDAY, APRIL 25.

The Determination of the Gastric Area, with Special Reference to Transposition of Viscera. Hour-Glass Stomach, Gastroptosis, etc.—Dr. A. L. BENEDICT of Buffalo, N. Y., stated that the gastric area was determined in a large degree by ordinary percussion, and occasionally by palpation. Succussion, which was really a form of palpation, was also employed, especially when the stomach was dilated and partly filed with liquid and gas. In succussion we palpated not so much the stomach as its contents, and it was really a form of *ballottement*, familiar in the diagnosis of pregnancy and other conditions. It was liable to give confusing results, as we might fail to discriminate between the stomach and colon, and might infer too little or too great degrees of dilatation. Since 1893, Dr. Benedict said, he had relied mainly upon auscultatory percussion for the determination of the gastric area, and had verified the accuracy of the method by the *x*-rays, by outlines made before operation or necropsy, and in other ways. He had found the ordinary bimanual Cammann stethoscope, or a simple flexed modification of it superior to the monaural instrument and the various forms of the phonendoscope. In certain cases, as when the stomach and colon were distended and in close contact, and it was impossible to discriminate between the two by ordinary percussion or even by auscultatory percussion, he substituted the tuning-fork for the percussing finger, and in his office he often substituted for the percussing finger an electric buzzer with a hard rubber stem, in order to communicate a thrill to the stomach or other organ examined. The *x*-ray he resorted to only in puzzling cases. Inspection with the gastrodiaphane he did not regard as very reliable, and it was rather troublesome. Fluorescin solution had been used to intensify the illumination of the diaphane, but in his experience they had not perceptibly done so; neither did they afford practical results with the *x*-rays. Dr. Benedict then gave the history of a number of cases, illustrating the practical application of these methods in transportation of viscera, hour-glass stomach, gastric dilatation, and gastroptosis.

Dr. A. ROSE showed an illustration of the circumscribing gastrodiaphane of Kemp, by means of which he said the position of the stomach could be exactly located.

Dr. J. KAUFMANN said he preferred to rely on simple percussion and palpation, which he regarded as more accurate than any of the more complicated methods, and it required no apparatus.

A Comparison of the Methods of Lavage with the Syphon Tube and the Politzer Bulbs.—Dr. JOHN P. SAWYER of Cleveland discussed the comparative advantages of these two methods of stomach lavage. He stated that the application of the Politzer bag, recommended by Ewald and arranged by Kuttner, with a hard rubber connection-piece, was the most efficient simple form of aspirator. In using this apparatus, he found it best to have the patient in a reclining position, with the clothes well loosened. The food residue having been aspirated as completely as possible, a bulbful of solution, medicated as desired, was introduced slowly into the stomach, and free active manipulation over the anterior abdominal wall was made with sufficient energy to produce a considerable movement of the liquid within the stomach, resulting in a thorough cleansing, and bringing it in close contact with the cleansed membrane. The contents were then withdrawn with the aspirator, which until that time had been controlled by the hand. By this method, cleansing of the viscus could be accomplished more thoroughly and in less time and with less fatigue to the patient than by the use of the syphon tube.

A Case of Peptic Ulcer After Gastroenterostomy, Causing Gastrocolic and Jejunocolic Fistulæ.—Dr. J. KAUFMANN of New York reported this case, showing the specimen. The patient was a man, 48 years old, who in December, 1901, had a gastroenterostomy performed by Dr. F. Lange for the relief of increasing pyloric stenosis and the recurrence of haematemesis, in spite of all internal treatment. The pylorus was found thickened, and its posterior wall adherent. The anterior surface showed an area of marked thickening, and opacity of the serous covering. A retrocolic posterior gastroenterostomy was done. A very high jejunal loop had been taken, and since the angle caused by the fixation seemed rather acute, the afferent and efferent portions of the jejunum were connected by an enteroanastomosis. The patient made an uneventful recovery and improved for a time, but after three months his symptoms recurred, and he complained of severe abdominal pain. In October, 1902, he developed certain cerebral symptoms; difficulty in speaking and writing, defective memory, muscular tremor, exaggerated reflexes, bilateral papillitis, convulsions, and periods of unconsciousness, with complete amnesia afterwards. He gave an old syphilitic history, and on that account he was subjected to a long and vigorous treatment with mercury and potassium iodide. His cerebral symptoms gradually abated, but his abdominal pain increased in severity, and in the course of time he became a morphine habitué. Usually, his pain was located in the upper abdomen, but at times it radiated into the lower section. While it lasted, the transverse colon could be often felt as a stiff, sausage-like tumor. At times, the attacks recurred almost daily, with intermissions of perfect freedom. In November, 1903, the patient complained for the first time of a sulphurous taste and leeching, followed by vomiting large quantities of fluid fecal matter. Lavage of

the stomach was begun. The vomiting was not repeated, but the finding of fecal matter in the stomach became more and more frequent, and finally, during the winter of 1904-5 it became constant. The fecal matter was even found in the fasting organ, but usually it was present only after a meal. The patient could recognize its presence by the fecal belching, and verified it by the use of the tube. The patient was operated on in March, 1905, by Dr. A. G. Gerster. He found a connection between the posterior wall of the colon and the diverticulum of the jejunum, which must have been formed by traction. On section, this connection proved to be an open channel of considerable diameter between the colon and jejunum. Both were closed by Lembert sutures. The middle portion of the transverse colon was adherent above to the larger curvature of the stomach, and posteriorly to that loop of the jejunum which had been used in performing the primary gastroenterostomy. The colon was reflected, and after the removal of a number of adhesions, it became evident that another and larger connection existed between the upper surface of the transverse colon and the posterior wall of the stomach, which on dissection was also found to be an open channel uniting the cavities of the stomach and the colon. These two openings were also closed. Recovery seemed uninterrupted until the sixth day, when symptoms of perforation developed, followed by collapse. An immediate laparotomy showed that the perforation was caused by extending necrosis of the sigmoid flexure from the site of the Murphy button that had been inserted to connect the ascending colon with the sigmoid flexure. The case resulted fatally.

Dr. A. G. Gerster of New York said Dr. Kauffmann's case was a good illustration of the fact that the surgeon was often obliged to do his work under most hazardous and unexpected conditions, and where so many factors, such as the anesthesia, the respiration, the general condition of the patient, etc., had to be taken into consideration. In some instances even on the post-mortem table, where the element of time did not enter into consideration, the skilled pathologist had the greatest difficulty to establish the exact and true condition of affairs, and how much more difficult, then, was the task of the surgeon?

Etiology and Serum Treatment of Dysentery.—Dr. William H. Park of New York opened the discussion on this subject. He stated that so far as his experience went, as well as that of others, amebic dysentery was a very rare disease, excepting in those chronic cases that had been infected in semitropical or tropical climates. It was certainly rare in the United States, and practically in the whole middle and northern parts of North America. Throughout the temperate and colder parts of the world, in dealing with cases known as clinical dysentery—not ordinary diarrhea—but cases in which the stools contained mucus and blood, and in which there was tenesmus, with more or less fever, in that condition we could just as surely expect to find bacilli of the dysenteric group as we could expect to find Klebs-Loeffler bacilli in diphtheria. These bacilli had given rise to more or less confusion. In the more severe epidemics, of dysentery, occurring in Japan, Manila, and elsewhere, the Shiga bacillus was found very abundantly in the mucous membrane of the bowel during the height of the disease. In addition to these epidemics, there were milder outbreaks occurring throughout the world, due to a number of varieties of bacilli, which might be called paradysenteric, differing among themselves, and representing, perhaps, half a dozen or more different strains. The Shiga bacillus was very rarely found, excepting in cases of true epidemic dysentery. On the other hand, the so-called paradysenteric bacilli were met with in quite a number of cases of diarrhea—mild and moderate cases of so-called summer diarrhea, which presented no definite symptoms of dysentery. In many of those cases we could not find any Shiga bacilli after a most careful search, nor could we find them in so-called cholera infantum or that type of disease. In regard to the serum treatment of dysentery, Dr. Park said that many of the acute cases in this climate were so mild that when seen early and treated properly, recovery promptly took place, and the use of serum was unnecessary.

Dr. John H. Huddleston of New York said he had seen several cases which were of the type described by Dr. Park as paradysentery, and which ran the usual course, lasting about a week or ten days. The origin of the disease could not be discovered. The worst cases he had seen occurred in the middle of winter, although this disease was usually considered as one of warm weather. All the patients recovered without the use of serum. The treatment consisted of saline irrigations, with salol and castor oil internally, and morphine, when necessary.

Clinical Features and Medical Treatment of the Benign Stenoses of the Pylorus.—Dr. Henry L. Elsner of Syracuse, N. Y., said that benign stenoses of the pylorus might be either functional or organic. The latter might be either congenital or acquired. Functional stenoses were likely to be transitory, and met with in highly neurotic patients. In the congenital type of organic stenosis, the symptoms immediately followed birth, or could not be long postponed. No possible modification of the food relieved the symptoms when the stenosis was of high degree. Congenital incomplete stenosis of the pylorus was frequently the cause of chronic gastric disturbance which continued throughout life. Of the acquired organic stenoses, we had, first, the intrapyloric. These included chronic cicatricial stenosis; fibrotic stenosis, general and localized; hypertrophic stenosis, as described by Curvelhier; stenosis dependent upon ulcer; acute inflammatory stenosis associated with infection, deep-seated gastritis and acute poisoning; syphilitic stenosis; tuberculous stenosis; stenosis dependent upon non-malignant growths, and stenosis due to distortion or traction. Of organic stenosis of the extrapyloric type it was difficult to divine all the unusual and unexpected conditions which might give rise to them. In regard to the diagnosis, Dr. Elsner said it was rational to suspect stenosis of the pylorus whenever it was possible to demonstrate marked dilatation of the stomach, with perceptible lowering of the greater and lesser curvature, recurring peristalsis from left to right (peristaltic unrest), which might or might not be painful, and might be and frequently was associated with ballooning of the organ; with either a palpable mass or thickening at the pylorus, more or less splashing and further evidences of motor insufficiency, the latter made positive by means of the stomach tube, and such other refinements of diagnosis as were now used by all who studied these cases closely, which proved beyond peradventure the stagnation of food. The fasting stomach found distended and containing food remnants must always arouse suspicion. One of the leading symptoms of stenosis was vomiting.

Etiology, Diagnosis, and Treatment of Benign Stenosis of the Pylorus.—Dr. George Emerson Brewer of New York City presented this paper. He stated that in considering the clinical history of pyloric obstruction, it was necessary to keep in mind that we might and frequently did have two distinct groups of symptoms: first, those due to the disease which gave rise to the stenosis, and, second, those due to pyloric narrowing, and the resulting gastrectasia and chemical changes which occurred in the retained gastric contents. With the exception of those cases where a tumor could be palpated in the pyloric region, there were no physical signs that aided in the diagnosis in the early stages of benign stenosis. When gastrectasia occurred, however, physical examination frequently furnished important data, and inspection would often reveal the outlines of a dilated stomach through a thin abdominal wall. Occasionally, the greater and lesser curvatures could be palpated, and splashing might often be elicited at a time when the stomach should normally be empty. Distending the stomach with air or water would often enable the examiner, by percussison, to identify its limits, and thereby furnish a fairly reliable estimate of its size. In consider-

ing the treatment of benign pyloric stenosis, Dr. Brewer said the fact should first be appreciated that all the untoward symptoms of the disease were purely the result of a mechanical cause, and could only be relieved by re-establishing a normal connection between the stomach and intestine. It would be a waste of time to even consider drugs, massage, electricity and lavage, which at best could only be regarded as palliative measures. With the exception of the few instances in which the obstruction was so slight that the symptoms could be easily relieved by dietetic regulation, or in those exceedingly rare cases where the stenosis was due to a syphilitic ulcer or gummatous deposit, and which quickly responded to anti-syphilitic treatment, surgery, and surgery alone could offer relief to these patients. In perhaps no other class of diseases of the ailmentary canal had the results of surgical intervention shown more strikingly satisfactory results. It would sometimes be possible to remove the cause of the stenosis by operation; for example, when the obstruction was due to peritoneal bands or adhesions, to new growths or enlarged lymph nodes pressing upon the pylorus or the first part of the duodenum, to foreign bodies, or benign tumors of the stomach wall. In the majority of instances, however, it would be necessary either to enlarge the contracted pyloric orifice by a plastic operation, or to create a new opening between the stomach and small intestines. Digital dilatation of the pylorus had been abandoned by surgeons. The pyloroplasty of Heinecke-Mikulicz was gradually giving way to other more radical procedures, for the reason that recurrences after its employment were so frequent. The operation of Finney and posterior gastroenterostomy were the two operations employed at present for the relief of pyloric stenosis. Finney's operation, which consisted in enlarging the pyloric opening by a plastic operation which united the first portion of the duodenum with the adjacent stomach wall was the operation of choice in cicatricial stenosis when the tissues were not too much infiltrated. In all other cases, gastroenterostomy was to be preferred. As to the mortality of these operations, in capable hands, with the physical condition of the patient still fairly good, it should be below 6 per cent. in benign cases, and as a permanent cure might be expected in the majority of cases of benign stenosis thus treated, it was difficult to appreciate why the rank and file of the profession should not give their unqualified approval to this method of treatment.

Dr. S. W. Lambert of New York said he thought surgery was the only possible resort in the treatment of pyloric stenosis. In the differential diagnosis between benign and malignant obstruction, the history of the patient was more important than the physical signs.

Dr. Howard Lilienthal thought that gastroenterostomy had probably better not be performed in cases of benign stenosis, if one could possibly manage to restore the parts involved to a condition more closely approaching the normal, and pyloroplasty, preferably by the Finney method, was his operation of choice in those cases.

Dr. Edward Quintard of New York said he had repeatedly seen cases of benign pyloric stenosis recover under medical treatment. While he favored operative interference in proper cases, he was more conservative than formerly in turning these patients over to the surgeon.

Dr. J. Kaufmann of New York said he could not indorse the radical view of Drs. Brewer and Lambert regarding the necessity for surgical interference in cases of benign pyloric stenosis. The surgical treatment was not without certain disadvantages. Mikulicz was on record to the effect that his experience with peptic ulcer had made him very cautious in advising operation, and he now limited operative interference to those cases where it was absolutely necessary. Dr. Kaufmann said he had frequently seen patients recover from their symptoms of pyloric stenosis under appropriate medical treatment.

Onomotologia Gastrologica.—Dr. A. Rose of New York presented a paper with this title. The paper was a plea for purity and correctness of medical language among writers and speakers, the suggestions it contained being chiefly confined to certain terms employed in gastrology.

Election of Officers.—The following officers were elected: *President,* Dr. H. W. Bettmann of Cincinnati; *Vice-Presidents,* Drs. S. W. Lambert of New York, and John P. Sawyer of Cleveland; *Secretary* and *Treasurer,* Dr. Charles D. Aaron of Detroit.

ILLINOIS STATE MEDICAL SOCIETY.

Fifty-fifth Annual Meeting, Held at Rock Island, May 16, 17, and 18.

Dr. William E. Quine of Chicago, President.

The scientific work of the society was divided into two sections, medical and surgical.

Medical Section.

The Optional Disease.—Dr. Hermann Spalding of Chicago discussed the symptomatology and differential diagnosis of smallpox, and showed lantern slides made from photographs taken of patients at the Isolation Hospital, Chicago. He also quoted the statistics of the Chicago Department of Health showing the incidence and deathrate of the disease in vaccinated and unvaccinated persons, and described the methods of vaccination. He emphasized the exercise of caution in using a virus which was efficient. Failure to obtain a take was usually due to an inert virus, and sometimes to improper technique in vaccinating.

Pericarditis.— Dr. J. H. Bacon of Cleveland, Ohio, discussed the clinical history of the various forms of pericarditis, and described a new method of tapping the pericardium. A small trephine opening was made opposite the fifth intercostal space between the midsternal line and the left border of the sternum. The finger was inserted through this opening, adhesions were broken up, and the pericardium opened. In cases of purulent pericarditis, to prevent infection of the sternum and a subsequent osteomyelitis, the posterior surface of the sternum was covered freely with 10 per cent. iodoform-paraffin or wax. He also suggested that in cases of adherent pericardium the patient's life often could be saved by making a similar opening and loosening the adhesions between the two layers of the pericardium in the same manner as uterine adhesions were liberated. He detailed experiments on dogs that were carried on by him showing the feasibility of this procedure.

The Present Status of Serum-Therapy.—Dr. E. R. Larned of Chicago defined what was meant by serum-therapy, and then classified the sera as used in medicine under (a) curative sera, and (b) diagnostic sera. Classification of sera as to efficacy, (a) those of demonstrated efficacy; (b) those whose value appeared probable, but remained to be proved, and (c) those whose efficacy was *nil.* He described the methods used in the elaboration of sera, and gave a brief outline of the present status of the following sera: (a) Those of demonstrated efficiency, antidiphtheritic, antitetanic, antiplague, antistreptococcic, and sera for exophthalmic goitre. (b) Those whose value appeared probable, but remained to be proved, as serum for hay fever, tuberculin, antityphoid, antirabic, antitubercle sera, and antivenene. (c) Those whose efficiency was *nil,* as antipneumococcic sera, antiscarlatinal sera, antidysenteric sera, antivarioloid sera, antitoxin for cerebrospinal meningitis, serum for rheumatism, serum for syphilis, serum for anthrax, cancer serum, and leprolin.

Scrofula.—Dr. Henry G. Anthony of Chicago stated that scrofula was a factor in dermatology, the importance of which was variously estimated, chiefly because of the diversity of opinion which existed as to what was meant by the term. He emphasized the fact that scrofula was not tuberculosis. Children with tuberculosis of joints did not present the various lesions which occurred in the eye and skin of scrofulous patients. It required nose and throat lesions to produce the clinical picture of scrofula. These nose and throat lesions were not tuberculosis, and the nasal

and throat secretions did not contain the bacillus tuberculosis. Clinically and microscopically, the disease was a pyogenic infection of the nose and throat. Tuberculosis readily developed on the pyogenic infections, but this could never be determined clinically, and that was the reason so many believed that the disease was tubercular. When a chronic pyogenic infection of the nose and throat was present, it spread to the ear, eye, skin, glands, and bronchial tubes. The eruption of the skin which occurred from this spreading of pyogenic infection was impetigo and not eczema, of which two varieties were mentioned, one of which was a varicella-like eruption. Eczema might occur in scrofula, but the cases which were usually called eczema were really impetigo. The author had observed that sweating of the hands and feet was an important symptom in the disease. Scrofuloderma was subcutaneous tuberculosis, and lichen scrofulosorum was a tuberculous toxemia, occuring in all forms of tuberculosis. The severest of all cases were those in which the infection had extended to the bronchial tubes.

The Educational Treatment of Neurasthenics.—Dr. Charles D. Center of Quincy believed that cases of neurasthenia were increasing in number very rapidly. He showed that a rather definite percentage of the symptoms of a neurasthenic were illusory or hallucinatory in character, and also claimed that practically every phase had one symptom, complaint, apprehension, or fear, which predominated over all the others. This one predominating symptom he called the chief obsession, and stated that when this was overcome or removed all lesser symptoms were either abated or were entirely relieved. A number of cases of neurasthenia from the practice of the writer were cited, giving the chief obsession in each case, and the educational means used to remove this obsession. Reference was made to the use of strychnine in these cases, and it was found that the majority were made worse by its administration. The author emphasized the need of getting hold of the mentality of each case of neurasthenia, believing that it was more essential to treat the mind than the body.

Late Hereditary Syphilis.—Dr. R. R. Campbell of Chicago stated that in establishing a diagnosis of hereditary syphilis there were three points known as the triad of syphilis, which had long been looked upon as of the greatest value. These were Hutchinson's teeth, interstitial keratitis, and a particular form of deafness. These points were considered in their order. He reported several cases of late hereditary syphilis gleaned from the literature and others that had occurred in his own practice.

The Climatic Treatment of Tuberculosis, with Special Reference to Colorado.—Dr. Clarence L. Wheaton of Chicago spoke of the mortality from tuberculosis and the period of life at which death occurred during the last census year. He alluded to the necessity for enforcing laws relating to hygienic and sanitary measures, the establishing of State sanatoria for the care of the tuberculous poor, etc. He referred to the success of the Ottawa tent colony in the treatment of this disease, and said the tuberculosis problem was to be solved at home, based upon a study of conditions in Colorado, Arizona, and New Mexico. A knowledge of meteorological facts and climatic data was essential in prescribing climate.

Diet in Tuberculosis.—Miss Adelia Sater of Ottawa spoke on this subject, and, among other things, stated that the appetite was no reliable criterion as to the amount of food that might be taken and digested by the patient. Hygiene and diet were the foundation stones upon which might be constructed successful therapeutics in the cure of tuberculosis.

Indormescent Shocks.—Dr. Hugh T. Patrick of Chicago called these indormescent because they ordinarily occurred just as the patient was falling asleep. These shocks might be divided roughly into motor and sensory. Mild motor shocks, or simple starts, might be regarded as normal, but in some persons they reached a degree which was pathological, and in others attained a violence sufficient to make them worthy of medical consideration and special treatment. The sensory form might affect general sensation or the special senses. The manifestation occurred as a symptom of functional disease, and in the vast majority of cases was of no grave significance, although the shock was a most alarming sensation for the patient.

The Glycosuria of Hepatic Insufficiency.—Dr. Alfred C. Croftan of Chicago spoke of the frequency of sugar excretion in functional disorders of the liver, and pointed out the dangers of treating a patient afflicted in this way as a diabetic. He detailed the causes, symptoms, and treatment of this variety of non-diabetic glycosuria.

The Practical Significauce of Certain Symptoms in the Upper Abdomen.—Dr. J. F. Percy of Galesburg said that the overlooking in this region of the pathology on which these symptoms were based was one of the strange chapters in the history of diagnosis. The common symptoms were pain due to cholecystitis, ulcer of the stomach, and of the duodenum, together with the formation of gas due to inhibited peristalsis. Vomiting was also mentioned; but nausea was a more prominent symptom than the former. Bleeding was also to be noted as one of the symptoms. The significance of these could best be determined by percussion, palpation, and noting costal resistance, especially in the right side. Laboratory methods were of confirmatory value only. Alone they could not make the diagnosis. The periodicity of the attacks from ulcer of the stomach and the duodenum was insisted upon, as was also the fact that the cholecystitis or an ulcer of the stomach would account for many of the chronic lesions of the liver and the pancreas. Both of these facts were new to the literature of this great subject.

The Tuberculosis Problem in Illinois.—Dr. Homer M. Thomas of Chicago stated that the main factor in the solution of the tuberculosis problem in this State was to secure for patients an abundance of pure air. It was from the unpierced heights and limitless expanse of the tractless skies that came the life-giving ozone. Its presence in the blood brought renewed life and vigor. The flagging forces of nature found in its subtle chemistry the antithesis of decay. The sodden skin, the halting step, the lusterless eye, the clouded brain, were rejuvenated under its vitalizing influence. Tuberculosis in Illinois concerned sources of impure air. These were mainly the home and the workshop. Tuberculosis was a house disease. It depended upon the home for implantation, growth, maturity and propagation. The house was the granary of the bacillus. Houses of one kind and another were the ordinary means of spreading the disease. The house was the most frequent means, and the workshop next. This was so because it took prolonged intimate contact with a person, place, or thing that had been intensely contaminated with tuberculosis matter to give rise to implantation. Probably three-fourths of all cases of the disease conveyed from person to person were contracted in the home, and one-fourth through the workshop and environment. Homes should be made clean, dry, airy and bright. Buildings in which men and women were employed should be made sanitary and should have a correct standard of air supply and light supply. The highest conception of medical science to-day was in preventive medicine. The Illinois State Medical Society had taken upon itself the advancement of this great work by establishing the Ottawa tent colony.

Parenchymatous Keratitis, Iridochoroidal Form, with Loss of Both Eyes.—Dr. Charles H. Probst of Peoria read a paper with this title, in which he stated that if iridectomy was to accomplish anything, it should be performed early in the disease, before iridic adhesions had taken place, or before an advanced iridochoroiditis had a chance to develop. On several occasions he had performed iridectomy in the very beginning of the iridochoroidal form of parenchymatous keratitis, with excellent results. In summing up the case, he reported there were several interesting features re-

lating to it, which were temperature from 1° to 1.5° below the normal, and a very slow pulse. The therapeutic agents which were administered per mouth, such as salicylates, mercury, and potassium iodide, exterted no influence on the disease whatever. Subconjunctival injections of mercury and salt solutions had no beneficial effect on the eye until after the constitutional results of mercury had been attained by deep hypodermic injections. There was a sudden development of a secondary glaucoma after the eye had been doing well for six months. Destruction of both eyes, four years apart, occurred in a similar way. While the history and all other symptoms were negative, he thought the case was undoubtedly one of hereditary syphilis.

Mixed Infection in Consumption.—Dr. ETHAN A. GRAY of Chicago spoke of the necessity of recognizing the presence of more than one infection in pulmonary tuberculosis. Secondary or so-called mixed infections were the chief agencies in producing the symptom-complex consumption. As to the course of mixed infection, there was danger of mistaking it for la grippe, malaria, colds, etc. Occasionally pleurisy and broncho-pneumonia were expressions of mixed infection. Hemorrhage from eroded arteries was a factor in spreading infection. A diazo-reaction did not always mean a fatal prognosis. Treatment should be largely hygienic and climatic, but this was uncertain as far as checking the toxemia was concerned. He spoke of the value of streptolytic serum; amount administered, 10 c.c. daily, for six days; treatment was then discontinued until reaction had passed. Usually cough and expectoration would be diminished to a minimum, sometimes altogether. The phenomena of reaction were pointed out. Post-reactive findings were few or no bacteria. There was diminution in tubercle bacilli unless sputum was greatly concentrated; normal pulse and temperature. Severe cases only approximated the normal. Serum did not cure tuberculosis, but only cleared out bacteria and their toxins, leaving a better field in which to fight the tubercle bacillus. Seven cases were cited, in all of which the septic fever was materially influenced. In one case of advanced consumption fever was reduced from 103° to 99.5°; appetite and sleep returned, cough diminished, and expectoration as well. One case died without fever or expectoration three weeks after treatment was finished. Five cases showed marked improvement with return to normal temperatures, and better general condition.

Dr. F. C. VANDERVORT of Bloomington reported a case of poisoning from oil of wintergreen.

The License and Control of the Practice of Medicine in Illinois.—Dr. GEORGE W. WEBSTER of Chicago reported the failure of the bill introduced into the late Legislature to create a board of examiners, and noted the duties of the Illinois State Board of Health as a licensing body.

Some Phases of Disordered Metabolism in Nephritis.—Dr. RALPH W. WEBSTER of Chicago said that nephritis was primarily a constitutional disease, with secondary manifestations in the kidney. The close relationship between the findings in the so-called febrile albuminuria and those in typical nephritis were so marked that a common constitutional condition in each must be granted. All of the causative factors of nephritis produced metabolic disturbances which resulted in the production, of toxins, irritant poisons, changes in the properties of the blood, both physical and chemical, and various other pathological abnormalities, which, in themselves, caused irritative and later inflammatory lesions in the kidney resulting in nephritis. A large number of metabolic changes might be directly traceable to the nephritis itself. In this paper the author discussed only the points of chloride retention, edema, and uremia. The retention of chlorides in nephritis was granted, but its relation to edema seemed to the author still debatable inasmuch as present knowledge regarding the pathology of albuminuria and of edema was not sufficient to warrant the ascribing of a specific influence to the chlorides in edema, over and above that of other salts. A discussion of the relation of chloride intake to increased albuminuria was given in which the author concluded that in this connection NaCl may act as a specific. Concerning the theories of edema, those of Cohnheim, Kövesi and Roth-Schulz, and von Kiranyi received attention. The author showed the importance of osmotic changes in the production of this symptom of nephritis. The relation of the amount of water taken in had a double importance in increasing a hydremia and in increasing the work of the heart. With regard to the uremia, it seemed that one must at present accept the idea of Senator and assume that this condition is purely a group of symptoms brought about through disordered metabolism as a result of lesions in an insufficient kidney, which lesions had, in their turn, been caused by attempts on the part of the kidney to eliminate products of an abnormal metabolism, the result of a specific or non-specific toxemia.

Dr. CHARLES L. MIX of Chicago discussed the diagnosis of chronic nephritis.

Ocular Manifestations of Chronic Nephritis.—Dr. LEIGH E. SCHWARZ of Chicago read a paper in which he drew the following conclusions: (1) An ophthalmological examination should be made in all cases where nephritis existed or was suspected. (2) The non-existence of retinitis must not be inferred because visual disturbance is absent. (3) Ocular manifestations were invaluable where nephritis without albumin existed. (4) The severity of the renal symptoms did not influence those of the eye. (5) Retinal changes might occur before any definite clinical symptoms of nephritis developed. (6) Unilateral retinitis gave a relatively hopeful prognosis. (7) Retinitis might be the first indication of nephritis even in the later stage. (8) Prognostic value of the hemorrhagic type was not greater than that of other forms of albuminuric retinitis.

Medical Treatment of Nephritis.—Dr. ARTHUR R. ELLIOTT of Chicago presented the subject in the following practical order: (1) Treatment of chronic nephritis without dropsy; (2) treatment of chronic nephritis with dropsy; and (3) treatment of uremia. After discussing the subject at great length under the above heads, the author closed by saying that there was no room for pessimism in our attitude toward this disease, and while obviously there was no remarkable cure to be performed by any mode of treatment, careful regulation of the life, and attention to little details, would secure results which were unsurpassed in any of the chronic dystrophies. The two most important indications were to protect the patient from intercurrent acute disturbance, and maintain the compensatory adjustment in the circulation.

Ideals and Practices of the Medical Profession.—This was the title of the president's address, delivered by Dr. WILLIAM E. QUINE of Chicago. He stated that standards differed in different societies and even under different conditions in the same society. It was a fact of familiar knowledge that offences committed by physicians against the public conscience might be easily tolerated by their own organizations, but offences against the technical standards of the organizations themselves, although quite unnoticed by the community at large, were liable to severe and lasting penalties, especially if the culprit was of humble rank and without friends. Among misdemeanors of this kind he mentioned advertising in the public prints; the exploitation of remarkable cures and operations; the holding of patents on articles used in the practice of medicine; the pretense of possessing an infallible law of cure; and the acceptance by physicians of commissions on their prescriptions, or on needed appliances which they were instrumental in selling, or on the fees surgeons received for operations on the physician's patients. Such acts were always small and surreptitiousness made them mean; but he failed to see in them convincing proof of gross moral obliquity. Most of them were quite compatible with honorable standing in the community; and yet they were stigmatized, and properly so, by the unanimous vote of the organized profession of the country as derogatory to professional character and incompatible with honorable standing in the profession—and,

hence were subject to penalty within the organization and profession itself. On the other hand, when physicians violated the public standards of morality and thereby brought upon themselves public disrepute, their professional standing might be saved from challenge in medical organizations. Such discrimination was neither creditable nor defensible. A life sentence of ostracism should never be inflicted for mere technical transgressions, nor for any others except such as constitute *prima facie* evidence of depravity of heart.

What We Must Learn and Unlearn in the Treatment of Tuberculosis.—This was the title of the address in medicine, delivered by Dr. J. W. Pettit, of Ottawa. The author said it was now a well-established fact that climate was an unimportant factor in the treatment of tuberculosis. Because the medical profession had learned the utter futility of drugs in the treatment of this disease, their responsibility had not ceased. Physicians should guide patients when they do not treat them. A mistake had been made in regarding fresh air as the *sine qua non* in the treatment of tuberculosis. Nutritious food, regular rest, and exercise were each of essential importance. There was much to be learned in regard to the housing of tuberculous patients. As to the use of tents, it had been demonstrated that the tent was practicable in cold climates. It fulfilled the conditions most perfectly from a scientific standpoint. A practical point essential to success was the importance of an early diagnosis in this disease.

The following papers were also read and discussed: "Air Examinations, Importance and Results," by Dr. Adolph Gehrman, of Chicago; "Typhoid Fever," by Dr. G. G. Craig, of Rock Island; "Cases of Erysipelas Treated with Marsh Purslane," by Dr. H. C. Mitchell, of Carbondale; "Respiratory Oxidation Stimulants in Nephritis, Pulmonary, Dyspneic, and Allied Criss," by Dr. George F. Butler, of Chicago; "Syphilitic Meningitis in Children," by Dr. William J. Butler, of Chicago.

(*To be continued.*)

Philadelphia Neurological Society.

At a stated meeting, held April 25, Dr. R. V. Patterson reported "Two Cases of Korsakoff's Psychosis, One with Necropsy." The cases presented the characteristic phenomena of polyneuritis occurring in persons who had been addicted to the immoderate use of alcohol, with symptoms of mental derangement. In the one case, degenerative changes were found after death in the anterior horns of the spinal cord and in the peripheral nerves. The second patient was a woman about fifty years old, who, although considerably improved, still presented weakness in all four extremities and mental aberration. Dr. Wm. G. Spiller exhibited "A Case of Amyotrophic Lateral Sclerosis Associated with Long-Standing Anterior Poliomyelitis." Dr. Wm. Zentmayer exhibited "A Case of Unilateral Exophthalmos and Extensive Involvement of the Cranial Nerves." The protrusion of the eye, the right, had first been noticed with the advent of menstruation at the period of puberty, increasing each menstrual period, and also later during pregnancy. The upper lip was in a state of ptosis, and all of the ocular muscles, internal as well as external, were paralyzed. The optic nerve was atrophic. The opposite left eye, though not bulging and exposed, presented conditions similar to those in the first, though in much less marked degree. The right side of the face was anesthetic in the distribution of the sensory branch of the fifth nerve and somewhat paretic. The right side of the tongue presented wasting and fibrillary twitching. The soft palate on the right side was somewhat anesthetic, and not as active in the movement as the opposite side. A diagnosis of thrombosis of the cavernous sinus on the right side with extension to the opposite side and backward to the petrosal sinuses was made, and seemed the most logical explanation of the symptoms. Dr. Alfred Gordon exhibited "A Case of Exophthalmic Goiter." The patient was a woman about 40 years old, who first noticed weakness in elevating the eyes, later protrusion of the eyeballs, then enlargement of the thryoid gland, and finally palpitation of the heart, with tachycardia and tremor. The upper lids were retracted and they failed to follow the eyeballs in their downward movement. The case was considered as lending support to the view according to which the lesions of the disease are found in the medulla. Dr. Thomas J. Orbison read a paper entitled "Delusional Insanity of the Persecutory Type with Cyclical Relapses," and he reported an illustrative case. Drs. Charles S. Potts and William G. Spiller read a paper entitled "Pseudosclerosis (Diffuse Sclerosis), with the Report of a Case with Necropsy." He referred to a group of cases clinically presenting symptoms of multiple sclerosis, but anatomically exhibiting only induration of the brain and spinal cord, with microscopic evidences of increase of neuroglia. Drs. Charles W. Burr and C. D. Camp presented a communication entitled "The Causes of Triplegia." They referred to cases in which, in connection with hemiplegia attended with contractures, the opposite previously unaffected member becomes contractured, and after death intense thickening of the walls of the blood-vessels of the part, with obstruction of the lumen at times almost to the point of obliteration, is found in addition to the changes in the brain responsible for the primary paralysis. Similar vascular alterations were found also in a case of paraplegia supposed to be of simple senile type Dr. J. H. W. Rhein reported "A Case of Syphilitic Encephalitis and Double Hemiplegia with Necropsy."

Books Received.

While the Medical Record *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

Les Médecins au Théâtre de J. Vaniquel au Dix-Septième Siècle. Par le Dr. G. L. Witkowski. 12mo, 568 pages, illustrated, paper. A. Maloine, Paris, France.

A System of Clinical Medicine Dealing with the Diagnosis, Prognosis, and Treatment of Disease. By Thomas D. Savill, M.D. Volume 2. 8vo, pp. 704-1147, illustrated, muslin. P. Blakiston's Son & Co., Philadelphia. Price, $3.00 net.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending June 10, 1905:

	Cases	Deaths
Measles	770	18
Diphtheria and Croup	522	30
Scarlet Fever	152	13
Smallpox	1	
Chickenpox	120	
Tuberculosis	339	107
Typhoid Fever	40	10
Cerebrospinal Meningitis	52	57
Typhus Fever		
Yellow Fever		
Cholera		
Totals	1,805	205

Chronic Acetanilid Poisoning.—D. D. Stewart reports two cases of acetanilid addiction, one of them at considerable length, and refers to others in the literature. The symptoms in the severer cases of chronic poisoning by the coal-tar products are, he remarks, very similar as regards mental and physical debility. There are cardiac weakness, more or less pronounced cyanosis, and blood changes characteristic of the action of a hemolytic agent. But for the leucocytosis, the blood conditions would almost suggest pernicious anemia with their diminution of the erythrocytes and changes in their size and shape, the presence of erythroblasts, often in larger numbers than in pernicious anemia, of polychromatophilic cells, and of cells undergoing protoplasmic granular degeneration. There is usually a notable increase of blood plaques and a leucocytosis is common, the increase, it is reported, being usually in the polymorphonuclear elements. In Stewart's cases, however, which were uncomplicated, there were 37 and 35 per cent. respectively, of lymphocytes. He thinks that possibly in other cases there might have been some complicating disease influencing the leucocytosis and the proportion of polymorphonuclears. In Cabot's case, complicated with nasal carcinoma, while the blood had the characteristic chocolate hue, and the hemoglobin was therefore not estimable, there was a leucocythemia. Erythroblasts were lacking, methemoglobin was demonstrable in both blood and urine, and the patient's general condition was good in spite of evident cyanosis. Such a case might superficially suggest, he says, the condition that has lately attracted considerable attention, chronic cyanosis with polycythemia and enlargement of the spleen. The difficulty sometimes attending the diagnosis in these cases has been noted by others and stress has been laid on the characteristic anemia. etc.—*Journal of American Medical Association.*

The Osmic Acid Treatment of Tic Douloureux.—W. Wayne Babcock states that the efficacy of the injection of osmic acid seems to depend upon two factors; first, the thorough destruction of nerve filaments and adjacent tissues produced by the osmic acid, and second, the fact that the area of destruction becomes filled by a mass of scar tissue that is impermeable to sensory impulses. In a large number of cases the injection is followed by complete anesthesia and relief of the pain, lasting at least for several years. Sufficient time has not yet elapsed to warrant conclusions as to complete cures. In other cases the relief is only partial or temporary. Yet improvement or relief generally follows a second injection of the acid. Absence of decided improvement after the precise injection of osmic acid into the trunk of the affected nerve seems rare. There is no danger to the general system from the local absorption of the osmic acid after the operation. The technique is simple, but it must be precise. After an incision is made over the affected nerve trunk it is hooked up, and from seven to fifteen minims of a two per cent. solution of osmic acid is injected through several different punctures into the nerve. In many cases it is wise to inject five or ten drops into the foramina of exit of the nerve. The writer then cites the history of a case in which this treatment was followed by excellent results.—*Proceedings of the Philadelphia County Medical Society.*

Alkalinity of the Blood in the Acute Exanthemata.—Kireef tested the alkalinity of the blood in fifty cases of acute infectious diseases, including variola, varioloid, scarlatina, measles, rubeola, typhoid, typhus and sepsis. The reaction was determined by the use of Engel's alkalimeter and it was found that in these diseases the alkalinity was either normal or was slightly reduced. Typhus alone formed an exception to the rule as in this condition the alkalinity was always increased, and the author suggests that this point may be of service in differential diagnosis.—*Zentralblatt für innere Medizin.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ending June 10, 1905:

SMALLPOX—UNITED STATES

			CASES.	DEATHS.
California, Los Angeles	May 20–27		1	
Florida, Jacksonville	May 27–June 3		3	
Illinois, Chicago	May 27–June 3		18

THE TREATMENT OF INOPERABLE CASES OF MALIGNANT DISEASE OF THE ORBIT BY THE *X*-RAY.*

BY CHARLES STEDMAN BULL, A.M., M.D.,
NEW YORK.

THE ophthalmic surgeon has for years been searching for some method of treatment for inoperable cases of malignant disease of the orbit, or for rapid recurrence of the disease in cases already subjected to operation, which would promise something more certain and satisfactory in permanent results than extirpation by the knife. Hence, the claims made during the last few years for the various forms of radiotherapy, including the *x*-rays, in this class of cases, are of great interest to us. The writer has carefully studied the published reports of cases of malignant disease treated by the *x*-ray method, but he has not been very favorably impressed, partly owing doubtless to lack of detail in the histories of many of these reported cases; and some of them, it must be confessed, read like fairy tales.

Walther and Béclère have reported the case of a young man, who, having already undergone several operations for sarcoma of the inferior orbital margin, had recently had a recurrence with lesions so extended that further operation was considered impossible. The patient was then treated by the *x*-rays, and eighteen sittings, covering a period of four months, sufficed to cause a disappearance of all traces of the neoplasm.

Prof. Berger treated with equal success a very serious recurrence of a sarcoma of the face, which in spite of the most vigorous surgical intervention, including resection of the superior maxilla and ligation of the external carotid artery, recurred each time with the greatest rapidity. Under treatment by the *x*-rays, the tumor entirely disappeared.

Many of the cases reported have not contained any detailed account of the exact method employed, of the number of sittings, or of the time of exposure, and many of the reports of cases contain only a few important facts buried in a mass of merely speculative hypothesis.

When any new agent is introduced to medical practice, it is at once grasped with hysterical enthusiasm and the most extravagant claims for its value are advanced, most of which are never realized; and we have naturally learned to criticise very minutely the reports of results so obtained.

It seems, however, to be an established fact that the *x*-rays do sometimes exert a marked influence on carcinomatous growths of a superficial character, causing them to slough and disappear. It has not been possible, up to the present time, for us to measure with any accuracy the activity of the radial energy coming from the tube, and hence we cannot determine the dosage.

* Read before the American Ophthalmological Society at its Forty-First Annual Meeting, Boston, Mass., 1905.

We all admit that every case of malignant disease of the orbit, which has apparently not originated in or involved the adjacent sinuses, should be extirpated by the knife as speedily as possible. But the consensus of opinion seems now to be that when the neighboring sinuses are involved a complete removal of the growth is impossible, a recurrence of the growth is certain to appear, and with each repetition of the operation the return of the disease is hastened, and the life of the patient is by just so much shortened. On the other hand, in view of what we actually know of the action of the *x*-rays, it would seem not only wise, but our duty, after such operation by the knife as may be necessary, to expose the parts a certain number of times to the *x*-rays, in order, if possible, to destroy isolated cells or aggregations of cells in the neighboring parts which cannot be reached by the knife. It is stated on good authority that there has been a marked diminution in the death rate following operations on patients so treated. Reverting to the primary effect of the *x*-rays on malignant growths, there seems no doubt that epithelioma and carcinoma yield more readily to their influence than does sarcoma. Many cases are reported as benefited, but few have been completely cured. The tumors have shrunken and grown smaller, but the patient's general condition has not improved. The writer has also seen it stated in print on several occasions that metastasis is more common in cases treated by the *x*-rays than in those subjected to the knife.

The writer's experience, based on his own cases in which this treatment has been employed, has satisfied him that the pain so constantly complained of, has been speedily, sometimes immediately, removed by exposure to the *x*-rays, and if this is repeated a number of times the pain does not return.

Therefore, in inoperable cases, whether from extensive spread of the disease, or for other reasons, this method of treatment is to be recommended to patients, because it relieves much of their suffering and thus may prolong their lives. It would seem that the more recent and superficial a malignant growth is, the more rapid and favorable are the results from the *x*-ray treatment, but it takes time to prove the ultimate good results.

The writer has not himself observed any of the dangers or evil effects of the *x*-rays which have been from time to time reported, in any of his own cases, such as infiltration and opacity of the cornea, optic neuritis, conjunctivitis, and cellulitis of the eyelids. Several authors have reported subcutaneous extravasations of blood, and Ehrmann has described a teleangiectasis appearing as a late result of exposure to the *x*-rays.

The writer presents the detailed reports of ten cases from his own private practice, in which the *x*-ray treatment was employed after excision by the knife. Of these ten cases, two were very much improved if not apparently cured, and of these two one was an epithelioma and the other a carcinoma. The remaining eight cases, in which no demonstrable effect was produced by the *x*-rays, were all

sarcomata. In the two favorable cases, showing entire disappearance of the growth under the influence of the radiotherapy, the writer did not observe any evidence of the marked cachexia so frequently reported in cases of malignant disease treated by this method.

There seems to be but little doubt that the *x*-rays do act favorably upon superficial carcinomata, and that the efficiency of the rays rapidly grows less with the depth from the surface. Our knowledge of the subject and of the real extent and nature of these rays is but scanty, and can be rendered accurate only by further experience.

Case I.—Myxosarcoma of the orbit. Gentleman, aged forty. Growth involved floor and inner side of left orbit. No apparent involvement of ethmoid cells, nasal meatus, or frontal sinus. Exophthalmos forwards and outwards. Apparently entire mass of infiltrated orbital tissue removed, leaving eye in place. Orbital plate of ethmoid intact. Relief of all symptoms for fourteen months; then return of growth as small nodule at infero-nasal angle of the bit. Patient refused further operative interference. Tumor grew very rapidly, so that in two months after its appearance the exophthalmos was extreme, and the growth filled entire orbit and extended down upon the superior maxilla and upwards upon frontal bone. Complete immobility of eyeball, ulcer, and perforation of cornea from total anesthesia. Constant severe pain which was almost immediately controlled by exposure to the *x*-ray treatment. In all twenty-eight exposures, beginning with ten-minute sittings on alternate days. Cessation of pain after second exposure. After the fifth session treatment applied only once a week, which sufficed to check the pain, so that patient suffered merely from slight dull ache in orbit. No apparent effect produced by the *x*-rays upon extension of growth, which eventually filled nasal meatus and pharynx. Patient died from exhaustion eleven months after reappearance of tumor, and two years and one month after first operation.

Case II.—Fibrosarcoma of periosteum of orbit and superior maxilla and of eyelid, without any involvement of skin. Gentleman, aged twenty-three. Beginning in floor of orbit and of very rapid growth, extending upwards and backwards in the orbit, and outwards and forwards upon superior maxilla, within six weeks after its first appearance. Eyeball not involved. Operation for removal within two months of its appearance, the skin of lower lid and eyeball being left *in situ*. Growth involved entire floor of orbit and extended for an inch and a half beyond lower orbital margin upon superior maxilla. It was not encapsulated, and as operation progressed it was found that it would have been wiser to remove the entire contents of orbit, including the eye and the periosteum, but to this the patient had not given his consent. After careful irrigation of cavity, the floor and inner wall of orbit and external surface of maxillary bone were cauterized with the galvano-cautery, and the skin-flaps were replaced. Patient made a rapid recovery and remained free from any sign of return for nearly sixteen months. A nodule then appeared at inner canthus and grew very rapidly in all directions and caused intense pain. Patient refused further operative interference, but consented to a trial of *x*-ray treatment. The exposures were made at intervals of three days, of fifteen minutes' duration. After the third application the pain became very much less intense, and the interval between exposures was gradually increased to seven days. No effect was produced on the growth of the tumor. Patient died from pneumonia three months after the return of the growth, and nineteen months after the operation.

Case III.—Sarcoma of the orbit, sphenoid and ethmoid bones, and nasal meatus. A lady, aged forty-five. For twelve months there had been continuous pain in the right side of the head and face and in the orbit, starting in the upper jaw and extending to the right temporal and parietal regions. Progressive exophthalmos, the protrusion being directly forwards, with marked limitation in motility of the eye. The exophthalmos resisted all pressure backwards. Accidental discovery of total blindness in right eye. Pupil dilated and immovable. Fundus normal except for engorged retinal veins. No perception of light. Hard dense infiltration of orbital tissue filling entire orbit, involving roof, floor, outer and inner walls. Chain of enlarged glands behind the angle of the jaw and down along the sternomastoid muscle to level of crycothyroid region. Patient had had frequent bleeding from the nose and a profuse purulent discharge from right nostril for several months. Superior and middle nasal meatus filled with growth, which bled easily. Patient was told of the grave nature of the lesion and of the necessity of an extensive radical operation, involving the removal of bone and the resulting disfigurement, and she declined the operation. She was advised to try the treatment by the *x*-rays for the relief of the pain and the possible arrest of the growth. She received the *x*-ray treatment three times a week, beginning with an exposure of five minutes, and gradually extending the time of exposure to twenty minutes. There was almost immediate diminution of the pain after the first sitting, and after the sixth exposure its complete abolition. Little or no effect was produced on the growth of the tumor, though at times a retardation seemed perceptible. A piece of the growth was removed from the nasal meatus and prepared for microscopical examination, which showed it to be a small round-cell sarcoma. Patient lived for nine months after I first saw her, and died from what looked like an abdominal metastasis, but no autopsy was allowed.

Case IV.—Sarcoma of orbit, involving the ethmoid, lacrymal, frontal and superior maxillary bones. Gentleman, aged seventy-two. Painless protrusion of left eye for five months. Eye blind from cataract and fundus invisible. Pain subsequently began deep in the orbit. Eye protruded forwards, outwards and downwards, to the extreme outer canthus. At inner canthus could be seen a tumor, which was hard, elastic, and resisting, in bulk larger than the eyeball, with smooth surface and firm attachment to the periosteum of roof and inner wall of the orbit. Tumor was not sensitive, but when pressed backwards caused severe pain at apex of the orbit. Nasal meatus and pharynx apparently healthy. In view of the age of the patient I declined to operate, but advised him, if the pain became severe, to try the treatment by the *x*-rays. This he did, but without any effect in lessening the pain or in retarding the growth of the tumor. He began by an exposure of ten minutes twice a week, and gradually increased the time of exposure to twenty minutes and the sittings to three times a week, having in all twenty-seven sittings. He died from exhaustion at the end of four months.

Case V.—Carcinoma of eyelid, orbit, and eyeball. Gentleman, aged seventy. The growth had begun four years before by a small nodule in the lower lid, near the internal canthus on the right side, and had gradually extended into the orbit along the floor and inner wall, pushing the eye upwards, outwards, and backwards. When I saw him the eye was almost buried in the mass of the tumor, which had involved

the conjunctiva and cornea, and probably extended into the interior of the globe. The tumor also extended down upon the superior maxilla and outwards upon the malar bone. A piece of the growth removed from the inner surface of the lid was examined under the microscope and proved to be a rather vascular carcinoma of slow growth. On account of the age and enfeebled condition of the patient, I advised against operation, but suggested a trial of the treatment by the *x*-ray at his home in a distant city. This was carried out under my directions very faithfully by his family physician and a local surgeon familiar with the method. Beginning with semi-weekly sittings and five-minute exposures, the sittings were increased to three a week and the exposure to twenty minutes, and on several occasions to half an hour. The pain was relieved after the third sitting, and could always be controlled by a five-minute exposure. In all the patient had thirty-four applications of the *x*-ray treatment. Not the slightest apparent effect was produced upon the growth of the tumor. The patient died a little over a year after I saw him, from exhaustion.

Case VI.—Fibrosarcoma of the orbit and adjacent sinuses. A gentleman, aged fifty-six. About a year before I saw him the left eye began to protrude, he being at the time in perfect health. There was no limitation of motility and no pain or discomfort, and the vision was at first unimpaired. The exophthalmos slowly but steadily increased and the vision also failed, and he became conscious of a stiffness in and about the eye. When I saw him the eye protruded downwards, forwards, and outwards, and motility was abolished. The cornea was clear and the iris and pupil were normal. Vision was limited to counting fingers at three feet. The lens was clear and the fundus showed the usual appearances of papillitis. Palpation revealed a hard, irregularly nodulated growth beneath the superior orbital margin and on the nasal side, which could be traced some distance backwards into the orbit. Nothing abnormal was found in nasal meatus or pharynx. The patient was advised to have the entire contents of the orbit, including the eye, removed, and this was done on the next day. After enucleation of the globe, the growth was found to fill the apex of the orbit and encroached on the roof and nasal wall as far as the orbital margin. The orbital plate of the ethmoid was gone except for a few fragments, and the tumor filled the ethmoidal cells. The entire cavity of the ethmoid was curetted, and the periosteum was carefully removed from all the orbital walls. The hemorrhage was somewhat profuse, but was readily controlled, and then the entire orbital surface was cauterized with the actual cautery. The orbit was then packed with iodoform gauze and a firm bandage applied. The healing progressed very rapidly and there was but little suppuration. Nearly three months later the growth reappeared in the ethmoid bone, and after again curetting it thoroughly, I advised the patient to make trial of the *x*-ray treatment, as I was sure the growth would return. He began the sittings with a five-minute exposure three times a week, and the time of exposure was gradually increased to twenty minutes. After the third sitting there was no more pain, and it never became severe afterwards. The growth returned at the apex of the orbit in less than a month, and grew very rapidly in spite of the *x*-ray treatment. In less than two months it had filled the orbit and was extending down upon the cheek and upwards on the forehead. The patient died apparently from heart failure not quite eighteen months after the first appearance of the symptoms.

Case VII.—Small-cell sarcoma of orbit, ethmoid, nasal meatus, and maxillary antrum, of very rapid growth. A lady, aged thirty-nine. Eight months before I saw her the left eye began to protrude and its motility was impaired. There were at times sharp twinges of pain in and about the orbit. All the symptoms grew rapidly worse and vision was lost about two weeks before she consulted me. At the time I first saw her the left eye was crowded forwards, downwards, and outwards by a growth which involved the roof, inner wall, and floor of the orbit as far back as the fingers could reach. It also extended beyond the orbital margin in every direction, and filled the maxillary antrum, as was proved at the operation. The growth was smooth, hard, and non-sensitive. The lower half of the cornea was opaque, and the conjunctiva engorged and chemotic. The left nostril was occluded and the growth showed in the nasopharyux. The patient was told of the gravity of the case, and of the impossibility of a radical removal, but she decided to have as much of the tumor excised as possible, as a means of relief from the pain. The entire contents of the orbit were removed, including a small portion of the floor which still remained, and the antrum was cleaned out thoroughly. No attempt was made to remove any portions of bone, as all the bones of the face and the sinuses were involved. The patient remained free from pain for not quite two weeks, and then the pain, which was of a burning character, returned in the orbit and cheek. I then advised a trial of the *x*-ray treatment, and she began the sittings with ten minutes' exposure, three times a week. After the third sitting the time of exposure was increased to twenty minutes, and the sittings reduced to twice a week. The pain grew less during the second sitting and ceased entirely after the third sitting, and never returned in a severe form. The growth began to fill the orbit and antrum again within a month after its removal, and the radiotherapy did not produce the slightest effect upon the rapidity of growth of the tumor. The patient died from exhaustion, and from what I believe to be a hepatic metastasis, eight months after the operation. No autopsy could be obtained.

Case VIII.—Sarcoma of orbit, ethmoid, sphenoid, and nasopharyux. Young lady, aged twenty-six, in good physical condition, with protrusion of left eye and greatly impaired vision. The exophthalmos began about five months before I saw her, and at the same time she began to have difficulty in breathing through the left nostril. The symptoms grew rapidly worse, and two months before I saw her the vision of her left eye began to fail. The exophthalmos was forwards and outwards, and the motility of the eye was limited in all directions. The growth could be felt on the floor and nasal wall of the orbit, and protruded beyond the orbital margin on the nasal side. The left nostril was occluded and the growth presented in the posterior nares. There was constant pain, and a discharge from the nostril which was bloody and purulent. Vision was reduced to 10/200, and the ophthalmoscope showed a well-marked papillitis, with great edema and numerous hemorrhages. The patient was told that her only chance of relief was a radical operation, and that the tumor had so deeply involved the sinuses that a complete removal would be impossible. She consented to the operation, and the eyeball and contents of the orbit were removed with great difficulty two days later. The orbital plate of the ethmoid was removed, the ethmoid cells were thoroughly curetted, and a large piece of carious bone was extracted. The middle turbinated bone was removed from the left side, and a large mass of the growth was curetted from the superior nasal meatus. The growth was

found to extend into the sphenoid, which was also curetted, and considerable carious bone removed. The maxillary antrum was not involved, and the right eye and orbit were healthy. The patient made a good recovery and remained free from pain for nearly three months. Then the pain returned in the inner angle of the orbit and roof of the nose, and the growth soon after reappeared in the ethmoid. I advised against any further operative interference, and suggested a trial of the *x*-ray treatment. She began with a ten-minute exposure three times a week, and after the fourth sitting the pain disappeared and did not return until after the treatment was given up. She had in all forty sittings, extending over a period of four months. The growth seemed at times to be somewhat retarded, but was not arrested, and gradually the orbit filled up and the nostril became again occluded. She died sixteen months after the operation, from what was apparently an abdominal metastasis.

Case IX.—Carcinoma of the eyeball and orbit. A gentleman, aged sixty, complained of a growth on the right eye, which he had first noticed three weeks before I saw him. On the outer aspect of the right eye, in the temporal and inferotemporal region, was a large irregularly nodulated mass, projecting about five millimeters above the surrounding surface. It was whitish in color, but highly vascularized, and had already grown over the temporal margin of the cornea. It was non-sensitive, but bled easily, and was firmly attached to the conjunctiva and underlying sclera, R. E. V—15/30: L. E. V—15/15. The patient was told of its malignant character and was advised to have the eye enuclected. He went away and I did not see him again for a month. When he returned the condition was much worse. The growth had involved the entire outer half of the eyeball, extended into the iris and anterior chamber and closed the pupil. He declined all operative interference, and I advised a trial of the *x*-ray treatment. A piece of the growth was removed for microscopical examination, and proved to be a true carcinoma. This case was the first one of the series which showed any marked improvement from the radiotherapy. The patient had in all twenty-seven sittings, at first on alternate days, and afterwards twice a week. The exposures varied in length from five to twenty minutes. The pain ceased after the first sitting. After the seventh exposure the growth began to flatten and scale off from the exterior. The cornea did not perforate, but flattened with the rest of the tumor, and eventually the growth entirely disappeared from the exterior of the eyeball and the latter became atrophied and flattened. At the end of the treatment the eye resembled one that had become atrophic after a perforating wound, or after an iridocyclitis. This patient has been seen at intervals since the treatment was stopped, more than a year ago, and there is yet no evidence of a return of the growth.

Case X.—Epithelioma of the nose, eyelids, and orbit. A gentleman, aged thirty-seven, presented himself at my office with the following history: About a year before a small lump had appeared on the right side of the bridge of the nose, which soon ulcerated. It extended upwards towards the eyebrow and outwards to the inner canthus. It first involved the caruncle and then extended into the orbit and into both eyelids. When I saw him the inner two-thirds of both lids were involved and their ciliary margins were ulcerated. The ocular conjunctiva on the nasal side was infiltrated, and the growth had extended along the floor and inner wall of the orbit. Vision was normal, the media were clear, and the fundus was healthy. The patient complained of a constant dull ache in the orbit and side of the nose, but there was no severe pain at any time. The case was desperate, and any operation for the removal of the growth seemed to be contraindicated, on account of the great extent to which the eyelids and orbital tissue were involved, which would require a very extensive plastic operation afterwards. The patient consented to try what treatment by the *x*-rays would do, and this was begun at once. The exposures were on alternate days, beginning with a period of ten minutes and gradually increasing the time of exposure to twenty minutes. The number of sittings was thirty-four, and they extended over a period of nearly four months. The dull ache in the orbit gradually subsided, though there was always a sense of burning in the parts involved. After the sixth exposure a change was noticed in the appearance of the growth on the nose and in the lids. The swelling disappeared, the parts seemed to flatten out, and the excoriated edges of the lids became covered with a dry scab, which later fell off, leaving a colorless, cicatricial appearance. At the end of the treatment the infiltration of the nose, eyelids, and caruncle had entirely disappeared, and the infiltration of the orbital tissue had diminished and could not be felt by the fingers on the floor of the orbit. Motility of the eye inwards was distinctly limited, but the eyeball remained as it was in the beginning, with good vision, clear media, and a normal fundus. This patient has been seen at intervals since the treatment by the *x*-rays was discontinued, and after sixteen months there is no return of the growth.

THE TREATMENT OF RENAL INADEQUACY COMPLICATED BY AN APPARENT NEPHRITIS.*

By W. J. PULLEY, M.D.

NEW YORK.

In 1827 Richard Bright first made public his discovery that many cases of general dropsy which are associated with the secretion of albuminous urine, have as the original cause of the dropsy, a primary affection of the kidneys. Since that time chronic nephritis either with or without dropsy associated, has been the subject of a great deal of original research and study. But of late this study especially of the treatment of chronic nephritis, has been greatly stimulated to activity by the assertion on the part of a number of surgeons of recognized ability, that it can be, and has been, cured by purely surgical procedures. Assertions of this kind following the rule in all such cases, are received with the greatest amount of scepticism, and this scepticism deepens when one reflects for a moment upon the varied pathological phases of chronic nephritis. Edebohls claims to be able to cure any kind of chronic nephritis coming under his classification, viz., chronic parenchymatous, chronic diffuse, and chronic interstitial nephritis, which to a certain extent embodies all kinds of chronic kidney inflammations. He states further "that this cure is brought about by removing a barrier in the shape of the capsule proper, to the creation of a new and increased and more active blood supply to the diseased kidney." "The removal," he further states, "of this barrier by decapsulation, is followed by the formation on the most extensive scale possible, of a new vascular connection between the kidney and its fatty capsule." That this new vascular supply is formed, is denied by at least three observers who

*Read before the Section on General Medicine of the New York Academy of Medicine.

have had the opportunity to examine minutely kidneys that have been decapsulated some length of time before removal (Jewett, Cutler, and Bonez-Osmolowsky). These observers seem to have found but little connection between the blood supply of the new formed capsule and the kidney. That a new capsule, denser than the one removed, is formed after decapsulation is sufficiently proven by the observations of several observers, including Edebohls himself, Hall and Herxheimer, Johnson, and Ferguson. Edebohls further states that the probable manner in which the cure is effected, is by this new blood supply removing by absorption the products of inflammation, which might be the case if the exudate was comparatively recent, but this method of reasoning is hard to understand in the case of a chronic interstitial nephritis. This same thing might likewise be said concerning the increased nutrition brought to the kidney epithelia by this new formed blood supply, but here the etiology of nephritis is ignored, which cause still exists probably, and will be just as potent as ever against this so-claimed new blood supply, causing a return of all the symptoms after a certain length of time. The following facts are interesting, viz., that Edebohls arrived at the idea of treating chronic nephritis by decapsulation, by noting the fact that movable kidneys which were secreting urine containing casts and albumin ceased to do this when fixed; and Harrison and Israel, in cutting down upon the kidneys of patients apparently suffering from renal colic,—kidneys that were secreting albuminous urine,—found nothing to account for the symptoms of obstruction, and upon relieving the tension of the kidney capsule by puncture or slitting, observed that the urine cleared up and that the other symptoms likewise disappeared. Dr. Winfield Ayres, working in another direction, stated in a paper read before the Urological Society, in June, 1904, that beginning nephritis under certain circumstances could be cured by lavage of the kidney pelvis, and cites several cases which have shown marked improvement while washing out the pelvis of the kidney, originally begun to cure an existing pyelitis. His cases cited all secreted a urine, when first examined by him, containing albumin, casts, kidney, and pelvic epithelia, and had many general symptoms of mild urea poisoning. "The character of the urine greatly improved," so he stated, "and all of the general symptoms cleared up in the course of his treatment." In looking over the cases reported by Edebohls, 72 in all up to 1904, I find many of them unilateral, a condition that might exist in the beginning of a chronic nephritis, but certainly not likely to exist at the late time at which he operated on a great number of his cases. According to 500 autopsies looked up by Guiteras, both kidneys were equally affected. Kummel and Strauss, by catheterizing both ureters in nephritis, found both kidneys equally affected. My own experience does not entirely coincide with that of the above observers, as I found in at least one case of chronic diffuse nephritis the disease apparently further advanced in the right kidney than in the left, but this might be explained by the fact that the right kidney was movable to the second degree. I find likewise, in looking over the cases operated on, those described as chronic interstitial nephritis secreted urine of high specific gravity and contained a large amount of albumin and many granular and hyaline casts. This might be the case at the termination, or even rarely during the course of this kind of nephritis, but it is certainly not the ordinary history of chronic interstitial nephritis. It is a well-known fact that the results of urine examinations do not present an unalterable or distinct picture always of the type of chronic nephritis under observation, nor does a large kidney always mean a parenchymatous or diffuse nephritis, but may mean a nephritis where the involvement predominates in the interstitial tissue, but containing many areas of healthy kidney tissue enlarged from overwork. This kind of an interstitial nephritis may cause pain in the back, produce urine of high specific gravity containing casts and albumin, and might be helped by decapsulation, which relieves the pressure caused by a tense capsule giving the healthy part of the kidney room to functionate. Those who practice decapsulation on such kidneys give a temporary relief to the patient, but do not cure chronic interstitial nephritis. Such a concentrated urine, containing casts and albumin, I found complicated many of the cases of floating kidney operated on by Edebohls, and reported as cures of chronic interstitial nephritis. In looking over the cases of other observers I find the diagnosis of chronic nephritis based principally upon finding urine containing hyaline casts, epithelial cells from the kidney tubes, and albumin. These methods of diagnosis may do very well for the quick cure of chronic nephritis by surgical or other kinds of local treatment, but there is a question in my mind as to whether they are sufficient to thoroughly establish a true diagnosis of this condition. My belief is, in doubtful cases, that the diagnosis of any of the forms of chronic nephritis cannot be made by a few examinations of specimens of urine collected at random, but other things must be looked into, as symptomatology, diet, exercise, and the general physical condition of the patient. In other words, in order to come to a reasonably correct idea of the condition of the kidneys, repeated examinations must be made of specimens of twenty-four hour urine, its quantity being known. Information should likewise be had concerning the quality of diet, habits as to exercise, etc., and any other condition of the patient which might affect the kidneys either directly or remotely. Especially all causes which tend to congest the kidneys or put tension upon its capsule, such as nephroptosis, or any obstruction, inflammation, or irritation of any part of the urinary canal, or cardiac diseases, or pressure from without, as pregnancy, tumors, adhesions, and constipation must be eliminated before one can make an unerring diagnosis of chronic nephritis as such. Do not believe me to say that any of these conditions may not cause chronic nephritis if left undisturbed for a long enough time, but I do say that it is my belief that these conditions may cause simply a disturbance of the kidney function, probably by producing an increase of the internal kidney pressure and tension of the kidney capsule. Such kidneys may secrete urine containing hyaline, hyalogranular casts, *i.e.* hyaline casts with a few granules stuck to them, albumin varying in amount, a lessening of the quantity of urea to a certain degree, together with many of the subjective symptoms of mild urea poisoning, such as backache, headache, spots before the eyes, and nausea, and still there not be present a true chronic nephritis. In other words, I consider many of these cases giving symptoms and secreting urine of this kind in the beginning simply renal inadequacies, where the kidney is unable to functionate normally, probably on account of some mechanical obstruction, which obstruction being removed, the kidney does its work properly, but is not cured of chronic inflammation in the true sense of the word. It is incredible to my mind that when a true nephritis from any cause has advanced to that stage where the urine constantly contains casts of different kinds, and there is a lessening of its urea and solids,

with a marked secondary cardiovascular involvement present, with a pronounced anemia due to chronic poisoning, that any surgical procedure or local treatment can cure the pathological process that must necessarily be present. Decapsulation or even lavage of the kidney pelvis might produce a temporary relief at certain stages, and in certain forms of chronic nephritis where the tension of the capsule simply increases the symptoms, but that is all, unless the cause is at the same time eliminated, and even then this treatment at best can only help that part of the kidney which remains in a healthy condition. Guiteras suggests that decapsulation relieves the kidney tension and congestion, allowing a freer flow of blood, and in so doing takes the strain off the heart, reducing general arterial tension and clearing up anasarca. It is my belief that much of the anasarca in parenchymatous and diffuse nephritis is due to this increase of internal kidney pressure, as that part of the cortex of the kidney which secretes the watery portion of the urine is squeezed against an unyielding capsule and cannot functionate. I find in most of Edebohls' cases of decapsulation, that when this tension and pressure is relieved, anasarca, if present, immediately disappears, an object lesson conducive of enthusiasm for the time being, both in the surgeon and patient. Any one who has seen much of clinical medicine has observed hyaline casts and albumin disappear from urine when their presence was due to failure on the part of the heart after this organ had been treated successfully for its incompetency. It is common for the same thing to occur in fevers and anemia. In primiparæ it is not a rare occurrence to see general anasarca or edema, with scanty urine, which contains albumin and casts, and a lessening of its urea, with all the symptoms of mild uremia accompanying, and at term, or even before if the fetus is expelled, the urine clear up and all symptoms disappear, and the patient go on to repeated pregnancies with no signs of kidney trouble reappearing. That some patients go into convulsions, coma, and die under similar circumstances, or develop a chronic nephritis afterwards, is really not a proof that the first was more than a renal inadequacy, probably due to pressure by the gravid uterus, causing an increase of internal pressure and tension of the kidney capsule. That one person has more vulnerable kidneys, or kidneys less able to resist traumatism than another, cannot be successfully denied, for reasons of heredity, habits, hygienic surroundings, etc. That urine clears up and symptoms disappear very often in nephropexies for nephroptosis is abundantly proven by many cases now on record, the abnormal urine and symptoms in these cases being due probably to torsion of the kidney ligaments, ureters, and blood-vessels, causing increased kidney pressure and tension of the capsule. Arthur Tracy Cabot of Boston asserts that an increase of internal pressure in the kidney may be brought about by an obstruction to the outflow of urine, as occurs in enlarged prostate. He finds that a continuous drainage of the bladder in patients of this kind (who in addition are secreting urine containing casts and albumin, with mild uremic symptoms), caused all symptoms to disappear and urine to clear up. A patient who came under my personal observation with a small stricture of the deep urethra had the albumin and hyaline casts disappear from the urine and all the symptoms subside when the stricture was thoroughly dilated and straining on the part of the patient to void urine ceased. A constant irritation of the mucous membrane of the pelvis of the kidneys and ureters by the passage over it of urine rich in uric acid, oxalate of calcium, etc. (gouty urine), will, to my mind, if continued long enough, produce an increase of pressure in the kidney. Pyelitis due to an ascending inflammation or to calculi will produce the same condition. Any pressure from without on the ureters or blood vessels, such as tumors, adhesions, or constipation, will likewise produce the same condition, and as Schreiber states, palpation of the kidney will often produce albuminuria, caused, as he thinks, by direct pressure upon blood-vessels and lymphatics. Falkenheim, according to von Jaksch, reported a case of intermittent albuminuria due to pressure of a tumor on the left kidney. Thus it can be judged with a fair amount of certainty that decapsulation of the kidney, or puncturing its capsule, or performing any of the other manipulations, as lavage of the pelvis, or relieving an obstruction in any manner, does cure what often appears to be a nephritis, not a truly pathological one, but simply an obstruction to the normal kidney function, caused directly by an increase of the internal pressure of the kidney and tension of its capsule; in other words, a renal inadequacy. It is not claimed here that decapsulation, and even pelvic lavage, do not benefit any case of chronic nephritis, but, on the other hand, both of these methods do produce good effects in certain cases, but should be confined to their individual spheres of usefulness, which are necesasrily limited ones. Any case of renal inadequacy, due to kidney congestion or tension of the kidney capsule, may be benefited by decapsulation, and any case of renal inadequacy due to a pyelitis may be benefited by lavage. I will go still further and say that, in case of true nephritis, where many of the symptoms are due to capsular tension, as occurs in parenchymatous and diffuse nephritis, and as rarely occurs in interstitial nephritis, decapsulation will do good often. Pelvic lavage will do good, as Ayres states, in the beginning of true nephritis due to an ascending inflammation. Sir Andrew Clark, in 1883, first described renal inadequacy. He stated in describing this condition that the patient passes a normal or subnormal amount of urine daily, with less than 2 per cent. of urea and no casts or albumin, is puffy under the eyes, and suffers from other symptoms of inadequate functions on the part of the kidneys. Loomis states that the urine and urea both are in subnormal quantities in renal inadequacy. My own belief is that in renal inadequacy the urine may not only be lessened in quantity, but contain albumin and hyaline casts and epithelial cells from the kidney tubules, together with certain subjective symptoms, such as backache, headache, languor, loss of appetite, etc., without there being present an active pathological process as is commonly found in chronic kidney inflammations. On reading Dr. Ayres' statement that he was getting good results in cases of chronic nephritis by washing out the pelvis of the kidney several times a week, I began to treat a number of cases by this method. In selecting cases of nephritis for this kind of treatment I chose those who apparently had symptoms due partly at least to an increase of the internal kidney pressure, and others who had a positive nephritis of long standing without these symptoms. I soon came to the conclusion that cases of the latter kind, which might include nearly all cases of chronic interstitial nephritis, and many cases of parenchymatous and diffuse nephritis, were not benefited at all, but in some instances made worse. In a number of cases, however, of the first kind, which principally included cases of chronic parenchymatous and diffuse nephritis, who gave symptoms of backache, headache, nervous twitchings, and pains radiating down back and legs, I feel that some good results were gotten, as many of these

symptoms were relieved entirely in one case, but for how long I am not prepared to say, and allayed in others, as well as some improvement in the condition of the urine. In several other cases treated, where the internal kidney pressure was increased as a result of pyelitis, causing renal inadequacy, good results certainly followed this kind of treatment. The treatment consists simply in passing catheters, by means of the cystoscope, into each ureter once or twice a week, after which collecting about four cubic centimeters of urine from each kidney for purposes of examination, then washing out the pelves with a warm aqueous solution of nitrate of silver of the strength of one to five or ten thousand. Further treatment was to cut off all proteids from the diet and keep the patient at rest as far as possible. The only medication given was cathartics, when necessary, and Bashams' solution three times daily. I will state that the cases of true chronic nephritis which were treated by this method had been receiving various kinds of medication for a long time before this, with but little change in their condition.

Case I.—The first patient which I wish to call your attention to is a woman who has probably a chronic diffuse nephritis. Mrs. M., aged 32 years, Hungarian, housewife. Habits good in every respect. Always perfectly well until marriage. Patient was married nine years ago, six months after which she had a miscarriage. Six months later she became pregnant again, and at the fifth month developed all the symptoms of nephritis, which caused her to lose the fetus one month later, and confining her to the bed for six weeks. One year after this, became pregnant again, which resulted in the birth of a healthy child at term. There was no trouble of any kind during the time the patient carried this child. Patient had three other miscarriages after this, all due to kidney trouble. Since the last one of these the patient has been suffering with headache, nausea, backache, nervous twitchings, edema of the lower extremities, spots before her eyes, and constipation. The condition of the patient's urine before treatment was begun was as follows: Acid, yellow, cloudy, sp. gr. 1,018, urea 14 gr. to the ounce, albumin 6 gms. to the liter, numerous hyaline and granular casts, epithelial cells from the bladder, ureters or pelvis, and kidney tubules. The quantity of urine passed in twenty-four hours was about 35 ounces. August 23, 1904, the patient received her first treatment. She received eight treatments in all, the urine from four of which was lost. Blood pressure was taken by means of Janeway's modification of Riva-Rocci's sphygmomanometer, and seems to have risen, if anything. The urine was increased in quantity, but otherwise remained practically unchanged. Patient refused further treatment after November 11, saying that she felt a great deal better, and that her sleep was undisturbed by nervous twitchings. There was but little cardiovascular change in this patient.

Case II.—Miss M., aged 55 years, single, cook, born in Ireland. Alcoholic and venereal habits negative. Mother and father dead, cause unknown. One sister died of pleurisy. Always well up until one year ago, except for the fact that she was constipated. Patient has never been married. One year ago illness began, with headache, dizziness, spots before the eyes, and muscular weakness. These symptoms were soon followed by shortness of breath and edema of the lower extremities, which compelled her to give up her work. Physical examination showed pronounced vascular changes, some cardiac enlargement, with faulty compensation. Some edema of the lower extremities, but the other organs normal except the kidneys. Repeated examination showed the urine to be of acid reaction, cloudy, yellow, sp. gr. 1,018, urea 1 per cent., albumin large quantity, hyaline and hyalogranular casts, and renal epithelial cells from bladder; quantity in twenty-four hours, 45 ounces. This was probably a case of chronic diffuse nephritis. There were five treatments in all given this patient. The patient had not worked for many months previous to beginning this treatment, but felt so well about the middle of September that she again sought work. Shortly after going to work she fell and broke her arm, so had to discontinue treatment. This treatment seems to have produced but little change of any kind in the patient's urine or blood pressure.

Case III.—J. C., aged 50, housewife, married, born in United States. Drinks moderately of beer, venereal history negative. Father died at the age of 47 of typhoid fever, mother died of heart disease. Has several brothers and sisters and three daughters and one son all living and well. Patient has suffered from stomach trouble and constipation for years, otherwise perfectly well. Has had pain in the small of the back for about one year. One week ago patient began to vomit, felt very weak and dizzy, and immediately following this her breath became short and her legs began to swell. Heart dilated, failing compensation, and moderate arterial change. Patient was very anemic, but otherwise normal, except for swelling of the feet and chronic nephritis. Urine then was acid, yellow, cloudy, sp. gr. 1,018, large quantity of albumin, urea about 1 per cent., a few hyaline casts, and passing about one quart of urine in 24 hours. Treatment was begun on this patient on September 6. She had previously had no other treatment from me. This was probably a case of diffuse nephritis. In this case, after the first treatment—there being three in all—the albumin in the urine was greatly diminished. The patient did not return after the third treatment, but affirmed at that time that she felt as well as she ever did in her life. These three cases were treated at my clinic connected with the New York University and Bellevue Hospital Medical College. Blood pressure seems to have been changed but little.

Case IV.—Dr. Ayres' case, which the doctor kindly allowed me to see in consultation with him, and which he has permitted me to report here. "W. S. H., age 34, occupation clerk, came to the office June 20, 1904. His appearance was typical of one in the late stages of parenchymatous nephritis. He said that with the possible exception of a few pains in the back in December, 1903, and a urethritis fifteen years ago, he had been perfectly well until March 15, 1904; then, from a description of his symptoms, he apparently had had an acute attack of nephritis that came on after catching cold. From that time until June 20 he had had considerable edema, at times becoming quite pronounced. During May he had had three attacks of uremic convulsions. He had been troubled constantly by shortness of breath upon exertion, and at times had had considerable nausea. He said that there had been a constant uriniferous odor to his body. He was unable to walk over two blocks without resting, and said that it seemed impossible for him to stoop to pick up his shoes. From March until June 13 he had not done any work, but had remained in bed nearly all the time. He was on the diet and medicine usually prescribed in these cases. When he came to me he had been at work one week, and during that time he had become rapidly worse. I found that his legs were markedly edematous to above the knees. There was also an area of edema over the sacrum. Pulse 88 and of fairly high ten-

sion. Heart moderately increased in size; first sound roughened, second sound accentuated. Quantity of urine said to be 50 to 60 oz. per day. Urine quite cloudy, sp. gr. 1,020, becoming solid on heating. Microscopic examination showed a large number of granular and hyaline and a few blood and epithelial casts, with a moderately large number of pelvic and tubule cells, all in a state of fatty degeneration. He was treated twice a week, silver nitrate 1-8,000 being used, with the result that at the end of two weeks the casts had all disappeared. The albumin had decreased markedly, at that time being 50 per cent. by bulk, or 5 gms. to the liter, by Esbach's test. He continued treatment twice a week until August 5. The report of that date shows that no casts were found, very few pelvic and tubule cells, and the albumin reduced to 3½ gms. On the 12th a few granular, hyaline and epithelial casts were found on both sides; albumin 3 gms. on the right and 4½ gms. on the left side. On the 19th there were no casts found, and the albumin had dropped to 2 gms. on both sides. He contracted a severe cold on August 27, and on September 2 the albumin was 5 gms. From this date until the 28th there were usually a few granular casts found on both sides. The last treatment was given on September 28, but since that time I have kept a fairly close watch on him, and ever since there has been steady improvement. When he came to me he was on milk diet with toasted bread. He was also taking Murdock's liquid food. He was taking diuretin and nitroglycerine. I made no change whatever in his diet nor medicine. When he came to me he had been at work one week and was rapidly getting worse. Since June 20 he has lost three days from work owing to severe attacks of bronchitis. When he came to me he could hardly walk, yet during the latter part of September he ran his own lawn-mower, and thought nothing of sprinting to catch a train when he was a little late. November 21.—General appearance excellent; passes about 75 ounces of urine in twenty-four hours, but this large quantity may be due to the diuretic and the large amount of water he is drinking. Sp. gr. 1,014. Found very, very few granular casts after looking over four slides. Albumin, 1½ gms. to the liter. January 18, 1905.—General appearance, perfect health; pulse soft and normal. He has no symptoms pointing to uremia, headaches, or any other similar condition. Has had a constant cold since last November, and at Christmas had an attack of grippe. Lost one day from work at Christmas. Drinks a very large amount of water and passes about 75 to 100 ounces in the twenty-four hours. Sp. gr. 1,008; albumin, ¾ gms. to the liter; three granular casts were found in four fields. There were also a very few pelvic cells and one or two tubule cells."

The four cases above reported are undoubtedly cases of true nephritis, which apparently have been benefited by lavage of the kidney pelvis. I have, however, in my records the histories and treatments of several patients suffering undoubtedly from chronic interstitial nephritis, who not only received no benefit from this method of treatment, but, on the other hand, were apparently made worse, if anything, and refused to be treated further. They all complained that the treatment caused them to have severe pain in the small of the back, and in one case there appeared to be a temporary suppression of urine. This proved, however, not to be a true suppression, but was due to a constriction of both ureters, preventing the flow of urine from the kidneys to the bladder, causing severe pain in back and abdomen. This obstruction we encountered in attempting to catheterize the ureter, the pain in the back and absence of urine in the bladder appearing shortly after our manipulations. The patient was put to bed, hot applications put over the kidneys, and soon the pain ceased and the urine came in gushes. These were probably fibrous strictures, as it was afterwards found that several of the patient's joints had undergone a fibrous ankylosis.

In addition to the above, I wish to speak of two other cases which I consider renal inadequacies, due to an ascending inflammation, and are not cases of nephritis, properly speaking. They were patients of Dr. Bremerman, with whom I studied them. They were undoubtedly benefited, and, I might say, cured by lavage of the renal pelvis.

Case V.—Mr. S. This patient several years ago contracted gonorrhea, followed by prostatitis and vesiculitis, for which he was treated successfully by Dr. Bremerman. Two years later, which is the beginning of the present illness, patient began to have pains in the small of his back and head, and developed sexual impotence, with a generally depressed feeling. September 10 of this year patient's ureters were catheterized, and it was found that the urine from the right kidney contained many pelvic epithelial cells, hyaline casts, and much albumin. The urine from the left kidney contained no casts, but otherwise was similar to that which came from the right kidney. The patient was treated several times, with the result that the urine cleared up and the general symptoms disappeared. There was no further treatment then until October 20, when the symptoms returned. A casual examination of a specimen of this patient's mixed urine on September 10 would lead to the diagnosis of nephritis, which, to my mind, is incorrect, as the patient was simply suffering from a renal inadequacy, due to an escending inflammation. The urine record shows that the patient again got well.

Case VI.—Mr. Le C. This patient gives a history of having gonorrhea for a long time, which was cured, with the exception of a slight gleety discharge. This was likewise afterwards treated successfully, and patient applied to a life insurance company for a policy, but was rejected on account of his urine containing albumin. Patient then came to Dr. Bremerman for treatment, with the result that the albumin disappeared from his urine and the pain in the small of his back and other general symptoms were relieved. The record of his urine examination during the time he was being treated shows a constant improvement. He was discharged as cured by Dr. Bremerman on November 11, 1904, as the albumin had disappeared from the urine and subjective symptoms were no longer present.

In conclusion, it is my belief (1) that chronic nephritis is never cured by purely surgical procedures or any kind of local treatment so far known to me. (2) That many symptoms of chronic nephritis which are due to an increase of internal kidney pressure can be relieved by decapsulation. (3) That many so-called cases of chronic nephritis are simply mechanical interferences with the normal kidney function, and that the inflammatory process, if any, is of secondary importance. (4) That lavage of the kidney pelvis is limited in its good effects to two conditions only, viz., pyelitis from any cause which affects the functions of the kidneys by increasing its internal pressure, and, secondly, in parenchymatous and diffuse nephritis where there is a great deal of cellular débris, a concentrated urine, increased kidney pressure and tension of the capsule. If I might hazard an explanation of the seeming good results gotten by pelvic lavage, I would say that they are gotten in pyelitis by clearing the pelvis and ureters of irritating substances,

and in the parenchymatous and diffuse nephritis principally by reflexly influencing, as a counter-irritant does, the blood supply of the kidney, accelerating the sluggish current, expelling the more or less stagnant blood, thereby bringing to the organ fresh blood, which in turn stimulates the kidney epithelia to more vigorous action, and reducing the internal kidney pressure and capsular tension, and thus tending to re-establish the normal conditions. I am greatly indebted to Dr. Bremerman for performing most of the lavages for me, and to Dr. Ayres for many valuable suggestions.

945 Madison Avenue.

THE PROPHYLAXIS AND TREATMENT OF PYOSALPINX.*

By JAMES N. WEST, M.D.,

NEW YORK.

PROFESSOR OF DISEASES OF WOMEN AT THE NEW YORK POST GRADUATE MEDICAL SCHOOL.

It is characteristic of human nature to look lightly upon dangers or evils to which we are accustomed. A man engaged in a dangerous occupation soon becomes used to the danger involved in his particular calling and ceases to shrink from it; while, if suddenly confronted with a peril of a different kind, he quails before it.

The disease under consideration, although terrible in its character and far-reaching in its results, is a perfect illustration of this principle. We have become, from the very beginning of our medical studies, familiar with its presence, and therefore entirely too indifferent to it. Do we do all that is in our power to prevent it? I am sure that we do not.

It is with a feeling of sadness that one turns to this subject, on account of the contemplation of the suffering to which some of the most innocent and lovely of that sex are uselessly subjected. The profession should take up this disease and fight it as it has fought puerperal sepsis.

In an analysis of reports of many thousands of pathological examinations of tubal contents I conclude that 62½ per cent. of the cases are due to gonorrhea; and about 16 per cent. are the results of incomplete abortion; the remaining 21½ per cent. being of uncertain origin, a few undoubtedly arising from the pathogenic organisms conveyed to the

Fig. 1.—Pyosalpinx, posterior view. *a*, right tube and ovary exsected and wound closed; *b*, hole in uterus near right horn made with curette; *c*, incomplete exsection of left tube; *d*, healthy left ovary not removed; *e*, rent in broad ligament, where profuse bleeding occurred, showing method of repair.

tubes from other parts of the body, as tubercle bacilli, colon bacilli, bacillus lanceolatus, or other microorganisms. Some cases are due to the introduction of germs into the uterus by instruments or fingers. We must then assume that about 78½ per cent. of the pyosalpinx cases are possibly preventable.

*Read before the New York Obstetrical Society, March 14, 1905.

Let us consider the most frequent cause, gonorrhea. To go back to the source of most infections, we must trace them to the male, and here leave its treatment in the hands of the general practitioner and the genitourinary specialist. It is for us, however, to emphasize to them that the slightest trace of gonorrhea is a bar to marriage, and that if, in

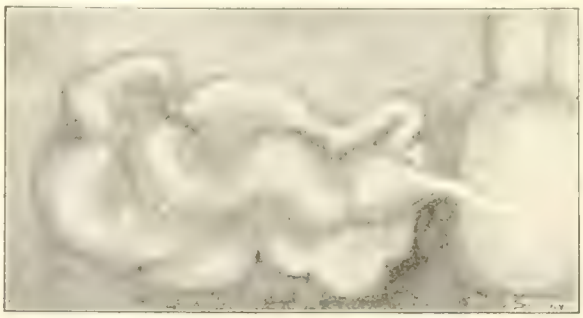

Fig. 2.—Pyosalpinx complicated with a very large appendix; posterior view. The uterus is seen in the center and above; the large appendix stretches over the pelvis; on either side and below are seen the diseased adnexa.

spite of this warning, the subject persists in having marital relations, he is subjecting his victim to the danger of a foul infection, which entails long-continued suffering, sterility, and possibly death. Let us all consider that the slightest inoculation of a woman should be taken seriously and treated most carefully and persistently until all traces of it have disappeared.

We will not dwell further upon the treatment of the more superficial infections, as upon those about the vulva, urethra, and glands of Bartholin. The disease must be fought from its very beginning up to what point? Many will say that we must go no further than the cervix, and that if the gonococcus beats us to the cervix we must admit that he has gotten into his hole and there the chase must cease and we must stand by, await results, and let the germ do its worst.

I am not yet ready to take this position. Curettage, of course, is out of the question here, as we would only open up fresh surfaces for infection and

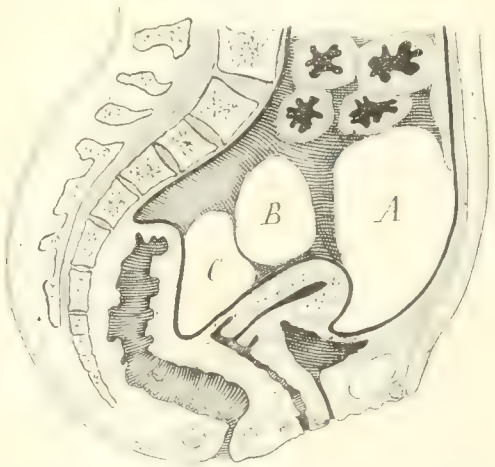

Fig. 3.—Complicated case of pyosalpinx; drainage; recovery. *A*, peritoneal cyst drained by gauze through incision in anterior abdominal wall; *B*, large pus tube on left side drained into vagina with gauze and later by self-retaining catheter sewed in place and removed after six weeks; *C*, peritoneal cyst in Douglas' cul-de-sac, first opened in exploring pelvis and drained with gauze. The right tube cannot be seen in the cut, but was in the same condition as the left and treated in the same way.

could look only for the worst results. I have treated two cases by washing out the uterus through a cervical speculum with an alkaline solution and following this with a solution of nitrate of silver, 1-240. In both cases great care was taken to first establish the fact that the uterus was the seat of infection, by making a microscopical examination of

the discharge under proper precautions. One of these patients I saw about two months after treatment had ceased, and there was apparently no discharge from the uterus and not the slightest evidence of invasion of the tubes. The other woman I lost sight of in a few weeks. She seemed much improved when I last saw her. If both these cases had been cured, I would not claim from them alone that the procedure was to be recommended, but I do not even know whether they were cured or not. I can only say that one appeared to be so, after two months, and that the other was improved when I last saw her, and that I feel encouraged to try the same treatment upon the next patient whom I find with a fresh gonorrheal invasion of the uterus. In addition to this, the usual dietetic and hygienic measures suitable for such cases were carried out.

Let us now consider the prophylaxis in the 16 per cent. of cases caused by infection following incomplete abortion. Opinion is much divided about the treatment of abortion. It is this very question which applies most closely to the subject of this paper, "Prophylaxis of Pyosalpinx." The evils of incomplete abortion, especially as related to pyosalpinx, have been so forced upon my attention at my clinics that my views upon this subject are very decided. I believe that in every case of inevitable abortion, the fact that the abortion is inevitable having been thoroughly established, the patient should be operated upon. If the cervix is already dilated, the operation of emptying and cleaning out the uterus with semi-dull curette or finger should be performed as soon as proper preparation of the patient can be made. If not yet dilated, the cervix and the top of the vagina may be packed with a 5 per cent. iodoform gauze, after thoroughly preparing the patient for this procedure, and then twelve hours later, or in less time, the operation may be performed. Before proceeding, when conditions permit, the bowels should be emptied and all the usual preparations for any serious operation about the vagina made. The only exception being where hemorrhage makes instant operation necessary. The patient should always be put under an anesthetic. If this plan be universally followed, there will be no cases of pyosalpinx following abortion.

The technique of the operation is most important. After curetting, one should be assured that the uterus is emptied by passing the finger into it. It should then be washed out with hot, boiled water, with a teaspoonful to the quart of Churchill's tincture of iodine in it. Packing with gauze is rarely necessary; but if hemorrhage should be considerable, I am in the habit of packing with a strip of 5 per cent. iodoform gauze, squeezed out once in a 1-1,000 bichloride solution, to wash out the excess of iodoform. The packing should be removed in twenty-four hours.

The cases of pyosalpinx caused by the introduction of dirty fingers or instruments or improper aseptic preparation about the labia and vagina are absolutely preventable through the practice of surgical cleanliness, and therefore such infections are inexcusable on the part of the operator.

Treatment.—The proper treatment for pyosalpinx is operation; but when, where, and how to operate has probably been the subject of more monographs and discussion than any other in the whole range of gynecological literature, thus emphasizing its importance.

When a patient presenting the symptoms of pyosalpinx consults me, I first obtain a knowledge of the stage to which the disease has progressed. In the more advanced cases, oftentimes, the walls of the tubes and ovaries and the plastic material deposited about them having yielded to the destructive influences of the invading microorganisms, melt down and coalesce into one large abscess having several communicating chambers. A patient in this condition should be operated upon as soon as proper preparations can be made, and the operation performed in the manner to be described later.

If, however, the case is one of the acute and virulent ones, and examination shows that it is not a suitable one for vaginal incision and drainage, the patient should be placed in bed for observation and local treatment. In addition to the general hygienic and dietetic measures which suggest themselves as suitable in such a case, an ice-bag protected by one thickness of flannel is placed over the lower part of the abdomen and there maintained by a bandage of woolen material passing over it and entirely around the body, thus keeping the cold to the part where its effect is desired and preventing a chilling of the body. Hot vaginal douches and rectal irrigations are made alternately every four hours. Under this treatment, the pain quickly diminishes and the pulse and temperature are lowered. There is, as a rule, no longer any necessity of administering anodynes. The inflammatory action is checked and exudate often diminishes.

This, however, is only a lull in the storm. In judging of the time to operate, one must remember that, provided the patient is not losing strength too rapidly, procrastination is, in one way, to her advantage, for as the disease advances, the organisms causing it are becoming less virulent. Bacteriological examinations of the contents of pus tubes at the time of operation have demonstrated that the virulence of the microorganisms and their presence is in inverse proportion to the duration of the disease. However, there comes a time when delay is certainly no longer advisable. The patient shows signs of failing and there is evidence that the disease is assuming a subacute and septic character.

There are several prominent operators in Germany who believe in delaying until this time on account of the lessened danger of infection; but, on the other hand, the tubes and ovaries and other tissues are being destroyed. I do not think that we should wait more than a few days in any case after the discovery of the disease until we operate. The use of peroxide where pus has been spilled so neutralizes the danger of infection from this source that it is no longer necessary to allow the disease to run a long course, waiting for the virulence of the infectious agents to die out.

Upon a case presenting the conditions first described, that is, where one or more large abscesses impinge upon the cul-de-sac, I adopt the following procedure: The patient being in the lithotomy position and the vagina retracted with a weighted speculum, the cervix is seized with a double vulsellum forceps and drawn towards the pubes, and an incision is made crescentic in shape and about an inch and a quarter in length and about a half-inch posterior to the cervix. The incision is continued upward in the axis of the pelvis until the abscess is well opened. Having then a free incision into the abscess, *not a puncture,* it is thoroughly washed out with a 2 per cent. carbolic solution and through a return catheter. Now, if thorough drainage is established and maintained for a sufficient length of time, a majority of such cases will make a good recovery. I sew a self-retaining rubber catheter into the opening with a No. 2 ten-day chromic catgut and pack the interior of the cavity lightly with iodoform gauze, using one strip on each side of the catheter and bringing the end of each strip into the vagina where they can be easily reached. This gauze is drawn

down gradually, so timing it that all will have been removed by the sixth day. The self-retaining catheter being sewed in place, remains, and by the time the catgut which holds it there has been absorbed, the opening in the vaginal vault will have contracted down so as to hold it in the desired position for any length of time. I believe that five weeks is usually long enough.

The above treatment is that usually adopted for pelvic abscess from other causes than tubal disease, and in it the question of effective drainage is solved by the use of the self-retaining catheter as described. The usefulness of this form of drainage, however, is by no means limited to the above class of cases. I have used self-retaining catheters to drain double pus tubes by the vagina in three cases, in all of which the results have been good. One was that of a young woman who had the misfortune to develop a double pyosalpinx as the result of incomplete abortion coming on in her first pregnacy. Both she and her husband were most anxious to have children, and I felt so disinclined to deprive her of any possibility in this that I resorted to the following expedient: Both tubes being distinctly felt to be enlarged, and the history indicating collections of pus, a good incision was made in the vaginal vault into the cul-de-sac of Douglas; guided by the finger, a long sharp-pointed pair of scissors was introduced into first one and then the other tube, evacuating the pus; each tube was then irrigated gently with a 2 per cent. carbolic solution through a return irrigator, then a self-retaining catheter was introduced past the neck of the catheter into each tube and sewed to the vaginal vault with ten-day chromicized catgut and cut off at a point just within the introitus vagina. The cul-de-sac was then gently packed with a 5 per cent. iodoform gauze wrung out once in a 1-1,000 bichloride solution. This gauze was placed in the space between the tubes and the end brought into the vagina. It was gradually drawn down, beginning at the end of the first 24 hours, until all was removed by the sixth day. This was done without disturbing the drainage tubes, as they were sewed in place, and also careful aseptic precautions were observed with every withdrawal of gauze; the outside parts, as well as the vagina, being first thoroughly douched with a 2 per cent. carbolic solution. The drainage tubes were left in place six weeks. This patient was operated upon about two years ago and there has never been any return of abscess. The woman enjoys excellent health. She has not conceived and may never do so; but had the operation been done by the abdominal route, in the usual way, she would have very probably lost her ovaries as well as her tubes.

A second case in which this method proved most useful to me was operated upon at the Post-Graduate Hospital about four months ago. This patient was 36 years old and had borne three children; the youngest was 11 years old. She presented herself at the clinic, having been ill two months. The cause of her infection could not be ascertained. There was nothing unusual in her menstrual history. She had complained of pain in the lower part of her abdomen and pelvis. Her temperature was at this time 102.5, pulse 110. Examination showed a large mass in the lower part of the abdomen and pelvis. She was sent into the hospital and put into bed with an ice-bag over the lower part of the abdomen, and hot vaginal douches given every four hours. Notwithstanding this treatment, she steadily grew worse. The temperature became more elevated and the pulse more rapid, and while the ice-bag controlled the pain, it was evident that her condition was rapidly growing more serious. Under ether, the mass appeared so large and of such uncertain outline, that I doubted the first diagnosis of pyosalpinx. The uterus could not be mapped out. The mass extended from the cul-de-sac to the umbilicus and into the iliac regions on each side. The cul-de-sac being full, I decided to explore it and make an incision into it through the vaginal vault. About a pint of clear fluid gushed away, causing me to think that I had opened into a cyst or into the abdominal cavity. However, higher up I could feel the ovaries and two large distended tubes. These were situated so high that I determined to open the abdomen from above and do a radical operation.

A three and a half-inch incision was made, whereupon about a pint and a half of clear fluid gushed out. The walls of the cavity were formed by the abdominal wall and omentum in front and coils of intestine, uterus, tubes and plastic material below and above. One could easily pick up large masses of lymph resembling pieces of fat. Having evacuated this cyst, I washed it out with one-half strength peroxide, and then with normal saline solutions. The great extent of this inflammatory area, and the firm character of the adhesions, caused me to give up the idea of a radical operation, and with the guiding hand within the abdomen, I incised the tubes through the vaginal incision, emptied and washed them out. The upper cyst was then lightly packed with gauze and the abdominal wound closed, leaving a sufficient opening at its lower part for thorough drainage. Then each tube was packed from the vagina with a separate strip of gauze, and another strip packed between them in the cyst cavity in the cul-de-sac, the three strips of gauze being brought into the vagina. This packing was gradually removed, and by the tenth day the abdominal cyst had entirely closed. By the seventh day all gauze had been removed from below, and on the tenth day the patient was lightly anesthetized and a self-retaining catheter sewed in place in each tube. One week later the patient was allowed to get up and was sent home with the drainage tubes still in position. Their presence did not seem to seriously impair her comfort or ability to move around. They were removed five weeks after they had been put in place. Now, four months after the first operation, this woman seems to be perfectly well. She weighs as much as she ever did, and a pelvic examination reveals scarcely a trace of the tremendous inflammatory process which had taken place. She now does all the light work of her household. It was, at the time, and still is my firm belief, that a radical operation would have resulted in her death.

My general plan of operation is to remove the tubes, leaving one or both ovaries, is possible. If the uterus seems to be in a necrotic condition—the seat of an abscess, or very badly injured in the course of the operation—it also is removed. The drainage method above referred to by me has only been used in special cases.

The general plan of procedure is as follows: If the cul-de-sac seems to be bulging with a large abscess, it is incised and washed out with a 2 per cent. carbolic solution; then the abdomen is opened and the tubes removed by clamping them off and tying the main vessels and sewing over the tops of the broad ligaments with a plain No. 2 catgut suture, and making a gauze drainage through the cul-de-sac into the vagina.

If the tubes are of such size or in such position as not to suggest a vaginal incision, the abdominal opening is at once made, the intestines freed from the lighter adhesions and the field of operation thoroughly walled off with abdominal tape pads, the patient being in Trendelenberg position. This done, the table is brought to a horizontal position, and the

removal of the tubes without rupture, if possible, accomplished. If this attempt be successful and there has not been very great traumatism and there is no great oozing, the abdomen is closed in layers with catgut, using No. 1 40-day, in the fascia. If, however, pus has been split, it is at once douched with a one-half strength peroxide, immediately followed by normal saline solutions. The enucleation is then rapidly performed while an assistant mops out the fluid.

Vaginal drainage of the cul-de-sac with gauze is always resorted to where there has been great traumatism, where pus has been split in the pelvic cavity, or where there is excessive oozing from ruptured adhesions.

It is only under exceptional circumstances and extremely rarely that any drainage is made through the abdominal wall. Injury to the intestines and complications with the appendix are very frequent; I believe, therefore, that in all cases where the tubes are to be removed, this should be done through an abdominal incision.

When requested to read a paper before this society, my mind turned to this subject, as being one of especial interest to me, and I looked over the records of my cases for one year past and found that I had operated upon thirteen. In eight of them vaginal gauze drainage had been used; in two the ovaries and uterus had been removed as well as the tubes; in one of these the pus had burrowed down between the vagina and the rectum, nearly to the perineum, and in separating the adhesions, two openings were torn into the intestines and closed at once. The complicated case, where extensive lesions prevented their removal, was the only one of the series where the diseased tubes were not removed. Complications were dealt with as met.

All cases recovered, and it is this fact which has caused me to go into the minute details of the operative technique used.

To sum up in conclusion, the following suggestions occur to me:

1. That all cases of abortion should be operated upon.
2. That gonorrheal invasions should be fought from their start to their finish.
3. That the greatest possible aseptic precautions should be used whenever the uterus is entered either by instruments or fingers.
4. That all cases of pyosalpinx should be operated upon.
5. That certain cases may be relieved by a proper form of drainage.
6. That an operator should not enter upon a case with a fixed determination to do a radical operation.
7. That the vaginal route is unsuitable for a radical operation.
8. That vaginal gauze drainage is the best form and has its definite indications and use.

FORMIC ACID IN RHEUMATIC CONDITIONS.

By LOUIS BRADFORD COUCH M.D.

Nyack, N. Y.

My attention has recently been called to accounts of the use of formic acid, or rather its sodium salt, as a "strength producer" of wonderful efficacy. As I have been experimenting with this remedy since August, 1902, I think it well to record my experiences, as they show that formic acid, exhibited as indicated below, possesses a therapeutic power of the greatest value and efficiency in the treatment of all kinds of rheumatic affections. Not only is it practically a specific for lumbago, muscular rheumatism, etc., but in sciatica it has proved in my hands to be a remedy of great power and rapidity of action. I never think now of treating neuralgia or muscular rheumatism with anything else. I have repeatedly seen acute inflammatory rheumatism with a temperature of 103.5° subside in from 48 to 72 hours. It is withal the only remedy that has proved of any practical permanent value in that dreaded, hopeless disease known as arthritis deformans.

On August 12, 1902, if I remember right, I saw in the New York *Sun* an account of the case of a Long Island bee farmer who had been speedily cured of chronic rheumatism by being stung by his honey bees. Being interested, I wrote the farmer, and received a speedy answer informing me that the statements made in the *Sun* were "so" in every particular.

I then began an investigation into the chemistry of the poison of the honey bee, and learned that formic acid was its main ingredient, and doubtless, I thought, its most important therapeutic constituent as far as the cure of rheumatism was concerned.

Procuring a pound of formic acid (c. p.), I began a series of experiments, which have shown that this drug is wonderfully effective as far as rapidity of action and relief of pain are concerned.

My first case was that of Mrs. S., 45 years old, a victim of arthritis deformans, who had been a helpless cripple for the better part of six and a half years. She had to be lifted from the bed to a rocking chair, and from the chair back to the bed, several times each night. She could not even turn herself in bed at night or help herself in any way. Her shoulders, elbows, fingers, ankles, and knees were ankylosed, the muscles being long ago atrophied from non-use. The knees were white, shiny, and swollen, and so sensitive to touch, pressure, or movement that, if the slightest twist or motion of knee or ankle were produced in dragging her about in her rocking chair, three hours of painful suffering was the result. As the patient said to me afterward: "Doctor, I often prayed that I might die, I suffered such agony and my condition was so hopeless and helpless. I could not sleep, being racked with pain night and day, with not even the power left to change my position to rest my wearied body."

I prepared a 5 per cent. aqueous solution of formic acid, and gave about 15 subcutaneous injections of 5 drops each, two and a half inches apart over the knee joints. These injections were very painful, but the pain lasted only about three or four minutes. In 48 hours all pain and suffering ceased, and the poor woman was enabled to get the first real rest and sleep she had had for years. This cessation of pain was so remarkable that the patient was highly delighted and I had hard work making her adhere to the regimen I vigorously insist upon in these cases. This is, (1) no drink of any kind during, or fro three hours after eating; (2) perfect mastication of all food and thoroughly mixing the same with saliva; (3) no coffee, pepper, mustard, acids, vinegar, or acid foods in general, sugar, pastry, cakes, stimulants, carbonated drinks, such as beer, vichy, seltzer, or soda water.

This first treatment was followed in one week with an increased mobility of all the joints, fingers, and a gradual decrease of swellings all over the body. Though the patient was formerly a perfect cripple she can now walk with assistance given, mainly to steady her. The limbs under friction and judicious exercise have become developed nicely in a muscular way. When I saw her first she could not raise her forearms above the elbows. She now, however, puts her hands upon her head, combs her own hair,

peels potatoes, sews with her needle, runs a sewing machine, and does a great many acts which a useful housewife finds necessary to do, and that, too, without pain or suffering. The patient has had several relapses from colds, exposures, or from using vinegar, pickles, etc., which were forbidden, and transgressing my medical laws as regards drinking during eating, but she has never failed to get beautiful results in 48 hours after any subsequent treatment. I have not, however, treated her more than five times in the last three years, and seldom use any medicine internally.

My second case was one of arthritis deformans of 23 years' standing, during 17 years of which the patient, a woman 53 years of age, had been confined to her chair or bed. She was able to sleep only in the early morning, the rest of the night being spent in being lifted from bed to chair and back again. I gave this woman at the first sitting about 17 injections of a 4 per cent. solution of formic acid, just beneath the skin in the most painful parts of the shoulder, arm, knee, and ankle of one side. In 48 hours she, too, lost all her pain on the side treated and the other side also was much benefited. One week later she received about as many injections on the other side of the body, and in 48 hours all pain of every kind left her and she could sleep all night like a top.

My third case was in a hotelkeeper who used beer freely. He had been suffering with lumbago for about three months. Could not stoop to pick up a thing from the floor to save his life. Had to roll over in bed very slowly and with great deliberation, and gradually assume the upright position. He had to be dressed and undressed by his wife. I gave him eight injections across the lumbar region in a double row. In 24 hours three-fourths of his pain had passed away, and in 24 hours more his pain was gone entirely and he could not tell where the injections had taken place. I saw him 48 hours after treatment. He smilingly showed me his ability to move in any direction, saying, "Just watch me; I can do all kinds of stunts now."

My next case was that of a woman who was afflicted with acute sciatic rheumatism. She came to me early one Sunday morning before sunrise. She could not rest, was suffering dreadfully, having had to walk the floor all night. I gave her about 10 injections along the line of the sciatic nerve just under the skin. In 48 hours she was well and never had another treatment and needed none.

My next case was in a woman, 61 years of age, suffering from arthritis deformans. She had had rheumatism since she was 16 years of age, a period of 45 years. She, too, was a perfect cripple. All her joints were ankylosed, her feet and hands being dreadfully deformed; knees were swollen, white, and very painful to touch or motion. She could not move or change her position, night or day, to rest or comfort her poor body. I gave her 22 injections of a 4 per cent. solution of formic acid subcutaneously, choosing the most painful locations for the exhibition of the remedy. The result was wonderful; all pain and suffering ceased in 48 hours and this condition continued for many months following, till one day she carelessly exposed herself to a severe draft of air during a storm, and her pains returned. She lived back in the country, and was so far away that I could not continue in attendance, and the patient passed into other hands.

On account of the severe pains experienced with formic acid injections I now use 8 to 10 drops of a 1 per cent. solution of cocaine at first, allowing patient to rest for 12 minutes. I then introduce into the same needle holes the formic acid injections. No pain whatever follows. In all kinds of rheumatism and neuralgias I have found formic acid a wonderfully efficacious remedy. It is not always a specific. It fails occasionally, why I do not at present know, but is is without doubt the best remedy I have ever used for this painful affection, and I am sure it will be many a long day before a better one is discovered. I have cured acute inflammatory articular rheumatism with a temperature of 103½° in 48 hours by exhibiting 32 injections as above.

The following case will also prove of interest, and I hope of value: Mrs. X., aged 64, was operated upon by me for epithelioma of the lower lip about two years ago. Six months afterwards I noticed a hardness in the point of union which gradually increased in size. It became quite painful on account of severe sharp, shooting, burning pains in the parts. I was confident the epithelioma was recurring. For an experiment I conceived the idea of injecting 8 drops of a 4 per cent. solution of formic acid into the growth to relieve the pain and stay the progress of the growth. The growth was "stayed" at once, became smaller in size, and all pain ceased at once, and though the experiment was made two years ago there has been no return of either growth or pain, and the parts are normal.

In conclusion I want to warn my readers against the use of formic acid in solutions stronger than 3 per cent. Strong solutions produce gray round eschars that are difficult to heal.

The following rules, based upon experience, will enable any one to use the remedy with perfect safety:

1. Always cleanse the parts thoroughly before injecting formic acid solution.

2. Never use a stronger solution than 3 per cent., and a 2½ per cent. solution is better.

3. Never use it without injecting 5 to 8 drops of a 1 per cent. solution of cocaine, or other local anesthetic as a preliminary to the formic acid treatment

4. I always choose extensor or outer parts of a limb for exhibiting the remedy and inject it just beneath the skin, though deep injections may be used when occasion demands.

5. I never use more than 8 drops in any one place of either cocaine 1 per cent. solution or of the formic acid solution. If I use 8 of the cocaine I use a similar amount of the formic acid solution.

6. If large doses are used of formic acid solutions, hard, painful lumps are formed which are slow of absorption and painful; whereas, if smaller doses are used no destruction of tissue results, and no hard, painful growths supervene.

7. I usually inject the most painful points I can find and make the injections not less than two inches apart.

8. I never have used more than 30 injections at a time, and it is far better to use only 12 to 15 and repeat the following day in another place. Avoid all nerve trunks, if possible, since injections involving nerves are apt to be followed by severe pains lasting for 24 hours. Injections may be given every day, or every other day, till all the pain has ceased. It will not be apt to return unless gross carelessness or wilful disregard of plain directions exist.

There is no artificial or animal digestive ferment that can supplant or take the place of a thorough mastication of food and mixing the same with saliva. A man who mixes food with drinks instead of saliva, washing his starchy food into the stomach where there isn't anything to digest it properly, will surely pay the penalty.

And let me give briefly here, just to put myself on record, the following facts, leaving for a later date the exposition of some interesting discoveries I

have made after four and one-half years of study and chemical analysis of the excretions in endeavoring to elucidate the causation of rheumatism: (1) All rheumatism, acute or chronic, muscular or articular, is due to self-generated systemic poison. (2) It is not bacterial. (3) It is chemical. (4) It is an acid and a suboxidation product. (5) It is not uric acid. (6) Uric acid is a product of, not the cause of rheumatic conditions. (7) Rheumatism is a product of starchy indigestion alone. (8) It is produced by fermentation. (9) It is caused by carbonic acid gas generated in the stomach and bowels, and is due to drinking at meals and washing the food into the stomach without proper mastication and thorough mixing with the proper ferments—the salivary secretions our Maker designed to digest such foods.

The Etiology of Infantile Eclampsia.—James M. French says that the term infantile eclampsia is used to designate a type of convulsive seizure rather than a condition peculiar to infancy. Some writers refer to the occurrence of the same kind of convulsions in adults. The writer considers the subject in relation only to infants and young children. In studying the etiology, an inherited or acquired predisposition and an immediate exciting cause must be considered When there is a history of similar convulsions, or of insanity, epilepsy, hysteria, or other neurotic disease, the predisposition is to be regarded as inherited. Alcoholism is a striking factor. Malnutrition is another important predisposing influence. The most vigorous child, however, with no hereditary taint, may be overwhelmed by either a chemical or mechanical irritant. The writer has not observed that sex has any influence. The Latin races are more susceptible than are any others. The exciting causes belong for the most part to one of two classes, namely, the direct or symptomatic, and the reflex. In the first class are those cases in which the stimulus acts directly upon the nerve centers. The most important stimuli are fever and toxemia. Anemia and altered blood-states, other than those produced by the toxic substances formed by bacteria and animal parasites are accountable for the eclamptic attacks in certain cases. Acute nephritis illustrates this. Ptomains are another example of chemical poisons which may act independently of fever. The most frequent of the reflex irritants is gastrointestinal disturbance. Over-distention of the stomach and improper food are common exciting causes. Certain forms of peripheral irritation are often referred to, as dentition, phimosis, masturbation, compression of the testicle within the inguinal canal, retention of urine, cutaneous eruptions, foreign bodies in the ear, and scalds and burns. Unless such irritation is very evident, all other possibilities should first be excluded. Careful examination of the disrobed body will sometimes give the cause. Cerebral congestion is the only explanation of some cases, as when the seizure follows crying, violent coughing, and so on. When convulsions in the infant are caused through the milk of the mother who has undergone some violent emotion, the influence should be regarded as a long-ranged reflex.—*California State Journal of Medicine.*

The Treatment of Menorrhagia and Hemoptysis by Inhalation of Nitrite of Amyl.—Horace C. Colman declares that amyl nitrite must be looked upon as a distinct help in the treatment of inaccessible hemorrhage. Hare has proved its usefulness in hemoptysis in a sufficient number of cases to warrant a far more extended use than it probably has at present. The writer tried this treatment in a case of severe metorrhagia, which he had found very difficult to relieve. The use of the drug was most successful. The writer believes that further trial in similar cases will meet with the same success. Doubtless the sudden lowering of the blood pressure is the main factor in the checking of hemorrhage by inhalation of nitrite of amyl. Clotting takes place in the bleeding area, whether this be ulcerated lung surface or engorged endometrium. The blood pressure rises again, but gradually, and so the clots formed are not dislodged. The action of amyl nitrite closely imitates Nature's method of checking severe hemorrhage—syncope, clotting in the ruptured vessels, gradual rise of blood pressure and return to consciousness. This method of treatment seems to have no bad effect on the patients. The headache that is usually complained of is very transient. In the case of menorrhagia cited by the writer, he directed the patient to go to bed as soon as menstruation started, and when there was more than normal bleeding, to inhale three minims of the drug. The results were eminently satisfactory, as the excess of bleeding was at once checked.—*The Scottish Medical and Surgical Journal.*

The Relation of Tetany to Gastrectasia.—James Burnet states that he has been struck with the comparative frequency with which he has found gastrectasia present in cases of tetany. Tetany is most commonly found in rachitic infants and young children, and apart from this gastrointestinal disturbances are often associated with it. In rickets dilatation of the stomach is often met with, and is due to the general muscular atony which is present in this disease. Improper feeding may also have something to do with this rachitic gastrectasia. The writer believes at any rate that the facts that tetany is usually found in rachitic subjects and that the latter generally present considerable gastric dilatation are significant and should not be altogether overlooked. He cites several cases in which tetany was associated with gastrectasia. The relief from the tetany in these cases practically coincided with the return of the stomach to its normal condition. It is possible that fermenting food in the stomach may give rise to toxic substances, and toxic products are bound to affect the body generally, and it may be the nervous system in particular. He thinks that in every case of tetany, attention should be paid to the gastrointestinal tract. The stomach should not be overfilled with fluid and fermenting foods. The stomach ought in every instance of tetany to be carefully examined by auscultatory percussion.—*The British Journal of Children's Diseases.*

Still's Type of Chronic Joint Disease in Children and the So-Called Tuberculous Rheumatism.—F. Parkes Weber, after referring to Still's gloomy prognosis in such cases, reports two. In the first, very great improvement took place, and in the second the affection appears to be relatively mild and quite stationary. The first patient is a boy, seven years and nine months old. Several years ago, the child was ill with what was thought to be articular rheumatism. Cervical rigidity developed, and about a year later there was an attack of endocarditis, and the heart began to show signs of mitral valve disease which have persisted since that time. The hands and feet became swollen, but attempts to obtain microbic cultivations from the swollen joints were not successful. The exudations were apparently gelatinous and into the periarticular tissues rathan than into the synovial cavity of the joint itself. The Röntgen ray showed no change in the bones at the articulations. The swelling of the hands and feet was symmetrical. There was apparent enlargement of the knee and elbow-joints. The spleen extended below the ribs, and the lymphatic glands in the neck, axillæ and groins were somewhat enlarged. The liver was also enlarged. It is now four years since the illness first began, and the child looks well and goes to school. The symptoms have subsided to a great extent. In the second case, Koch's old tuberculin was injected, and this was followed by a definitely positive general reaction. This did not appear to be accompanied by any local reaction in the joints. The writer states that possibly the primary cause of the joint condition may vary in different cases, but at any rate he regards the hypothesis that in at least some of the cases it is etiologically connected with tuberculosis as of extreme importance. Although it is not likely that a multiple symmetrical affection is due to the local presence of tubercle bacilli in the affected joints, it is quite possible that some cases are of the nature of what has been called "tuberculous rheumatism," that is, an affection set up in specially constituted individuals by toxins from tuberculosis in other parts of the body.—*The British Journal of Children's Diseases.*

MEDICAL RECORD.

A Weekly Journal of Medicine and Surgery.

New York, June 24, 1905.

SURGICAL SHOCK AND COLLAPSE.

SHOCK and collapse are factors that must be reckoned with in every surgical procedure. They are at times due to the condition for which the intervention is undertaken, but they are further materially contributed to by the anesthesia usually required. Additional influences are the various manipulations during the course of the operation, with perhaps exposure to the air of delicate structures and lowering of the bodily temperature. The result of an operation not rarely depends on the consideration given these several conditions. Accordingly it is incumbent on the surgeon to acquaint himself with the mechanism of shock and collapse and the means of prevention and treatment. In the Hunterian lectures just delivered before the Royal College of Surgeons of England (*The Lancet*, April 1, 1905), Mr. J. P. Lockhart Mummery defines surgical shock as a condition resulting from exhaustion of the vasomotor centers and the consequent great fall in blood-pressure. Collapse he considers a similar condition caused by lowering of the blood-pressure in consequence of hemorrhage or of paralysis of the vasomotor centers. Surgical shock is most common as a result of operations on the abdomen, the most important factors in its causation being injury to or exposure of the peritoneum, the time consumed by the operation, injury to organs richly supplied with nerve-fibers, evisceration, and extensive and prolonged manipulations. The most important factors in causing shock in connection with operations in other parts of the body are injury to large or important nerve-trunks or to parts largely supplied with nerve-endings, the extent of the wound, the time of exposure of the tissues, and hemorrhage. Ether alone or mixed with chloroform is the preferable anesthetic when there is danger of shock. The time required for operation is an important factor, especially in the cases of old persons and of children. So also is the condition of the patient prior to operation, particularly with respect to his nervous system.

In the prevention of shock the method of blocking the main nerves with cocaine seems to be a ready and efficient means except in the case of abdominal operations. Morphine administered, both before an operation and afterward, is useful to the same end. The blood-pressure should be observed during the course of operations in order that injurious influences may be discovered and avoided so far as possible, and that treatment should be instituted promptly when required.

In the treatment of shock stimulants are contraindicated, especially strychnine, as they tend to increase the severity of the condition and to retard recovery. The head should be lowered and the foot of the bed be elevated. Compression of the abdomen, either manually in case of emergency or by the application of a tight abdominal binder, is a most effectual procedure. The establishment of peripheral resistance artificially by the application of external pneumatic pressure is an assured method of maintaining the blood-pressure. The intravenous infusion of salt-solution or physiological serum is a means of raising the blood-pressure applicable to all degrees of shock. Its action, however, is transient and cannot be maintained indefinitely. The procedure is effectual against the collapse due to severe hemorrhage. The introduction of saline fluid into the abdominal cavity following an abdominal operation is a valuable method of combating shock and is not contraindicated by the presence of pus in the cavity. One of the most effective means of treating shock consists in the administration of drugs like adrenalin and ergot, which raise the blood-pressure by increasing the peripheral resistance independently of the nerve-centers.

PULMONARY TUBERCULOSIS AND CLIMATES.

THE belief that climate *per se* has little influence on the progress of pulmonary tuberculosis is perhaps gaining ground. This fact was emphasized at the recent congress of the National Association for the Study and Prevention of Tuberculosis, when the report of the committee on the rôle of climate in the management of tuberculosis was objected to by many present on the ground that too great stress had been laid on climate as a factor in the successful treatment of consumption. Dr. Lawrence F. Flick went so far as to state that in his opinion there was nothing in climate in the treatment of the disease. He believed that common sense ways of living in the open air, proper diet, and proper discipline in any kind of climate would effect a cure.

In the *Journal of the Association of Military Surgeons*, for June, 1905, is an article by Dr. Edward D. Sinks, late Contract Surgeon in the United States Army, on the diagnosis and course under favorable climatic conditions of pulmonary tuberculosis. He first dwells at some length, and with much emphasis, on the need of an early diagnosis of the disease if a successful outcome is to be expected. There is but little doubt that an early diagnosis is one of the most important factors, if not the most important, in successfully treating consumption. This point, however, is so fully recognized and has been so thoroughly discussed that it would be superfluous to enlarge upon it.

Dr. Sinks thinks that patients, as a rule, do not give treatment in the West a sufficiently long trial, and that, therefore, they should come with the idea of making their home in the West for the time being. He does not believe in the "roughing it" system, and ranch life in the West is about as rough and uninviting to the sick as any mode of life could be. It is next to impossible to secure eggs and milk, and canned food is the supply upon which chief dependence must be placed. The writer, therefore, advises those suffering from pulmonary tuberculosis to go to the West with the idea of living in town or city, and of being in the open air as much as possible. Living in a suitable tent is recommended.

All authorities are agreed that in the treatment of consumption, open air, nutritious food, and a routine manner of living are necessary to successful results. A dry climate is probably of the greatest benefit to the majority of patients, but the personal equation must be always considered. If the choice lies between climate and good food and attention, the question of climate is of lesser importance. A sufferer from pulmonary tuberculosis when well looked after in a damp climate stands a far better chance of recovery than does a consumptive in an ideal climate who does not receive proper food and good care.

On the whole, it may be said that the question of climate is losing importance in the eyes of most phthisis therapeutists. The crux of the problem of treating consumptives most advantageously, after all, is in home treatment. There are thousands suffering from consumption in its early stage, who, if the disease were promptly diagnosed and efficiently treated, would recover. The home treatment of consumption, however, cannot be successfully pursued on a large scale until the conditions of life of the poor in large cities are radically altered. Provide thoroughly sanitary dwellings, and plenty of open spaces in our large cities and the most important step in the crusade against consumption will have been taken. In the meantime, the battle must be fought with the best weapons at hand, of which climate, although an effective one, is less easily reached, and, in fact, less to be considered than some others.

Yellow Fever in the Isthmian Canal Zone.

The occurrence recently of several cases of yellow fever among the workers concerned in the building of the Isthmian canal, although not especially alarming, gives further emphasis to the numerous statements that the first and paramount duty of the United States Government is to insist upon a thorough sanitation of the entire district through which the projected canal will pass. The experience of the Lesseps Company clearly showed that the worst obstacle to be encountered in the construction of a Panama canal was disease. The climate of the canal zone is naturally unhealthy, and, of course, the conditions there are greatly aggravated by physical causes, but there would seem to be no valid reason why, if the Health Department at Panama is given a perfectly free hand, the district should not be rendered as little injurious to white men as many other parts of the Tropics. Colonel Gorgas has demonstrated his ability for such sanitary work by the cleansing of Havana, converting that town of evil repute into a salubrious place of residence for white men. He would doubtless have shown much better results by this time had he not been so hampered in his work by officers and ignorant laymen in the old Canal Commission, but there is promise of improvement in the attitude of Gov. Magoon of the new commission. "I know I voice the earnest conviction of the President and the Secretary of War," writes the Governor to Colonel Gorgas, "in saying that yellow fever must be eradicated and proper sanitation accomplished, if it is within the power of human endeavor. Money, means, and men, to the extent of the Commission's ability to supply them, are at your disposal. We rely upon you to ascertain and determine what is required. By 'we' I mean the President, the Secretary of War, the Commission, and the people of the United States." There is a ring in this that sounds very different from the objections of the Grunsky régime, and Colonel Gorgas knows that at last the opportunity is his to show what he can do. In spite of the vastly greater difficulties of the task, we doubt not he will eventually triumph as signally as he did in Havana.

The Fish Theory of Leprosy.

There are few scientific men who have investigated into the origin of leprosy who believe that the consumption of tainted fish is a factor of consequence in its causation. However, Mr. Jonathan Hutchinson is a dissenter of such note from the views ordinarily held concerning this disease that his opinions have been listened to with more or less patient attention. In the *Journal of Tropical Medicine* of May 15, Mr. Arthur Neve of Kashmire, India, again discusses the well-worn subject. With regard to the etiological connection between Christianity and leprosy suggested by Mr. Hutchinson, the writer shows by a mass of evidence that Catholics in India suffer no more from leprosy than do the members of some sects whose consumption of fish is small or nil. Mr. Neve, indeed, maintains that it would be erroneous to assert that native Christians connected with the Roman Church eat more fish than their neighbors. The writer asserts that judging from his personal experience in India, which has been a wide one, he has received no proof that eating decomposed fish has anything to do with the causation of leprosy. Mr. Neve states that in the course of a recent prolonged tour through India he has found a distinct consensus of opinion against the fish theory. He further states that a belief in some form of commensal contagion seems widespread, and is gaining ground; and finally he says: "It is generally felt in Indian circles that Mr. Hutchinson, acting on preconceived notions, has rejected as unreliable the witnesses against his theory; that there are few localities where any modification of the fish theory covers all the facts, and many places where it is in opposition to most of the facts."

Still Another Etiological Theory of Appendicitis.

Mr. Campbell Williams, in the *Clinical Journal*, of May 17, adds one more to the numerous and weird theories which have been offered in the last decade in explanation of the origin of appendicitis. He is of the opinion that appendicitis may be due to a food preservative—boracic acid. He argues that this drug is the most commonly used food preservative, and that it is more or less freely added to milk, cream, butter, meat, fish, and even soups. These articles of food are largely ingested during warm weather, when appendicitis occurs most frequently. It is well known that boracic acid, when given in small doses for a short continuous period, has peculiarly irritating effects on the alimentary tract. An inflamed mucous membrane affords the opportunity for the bacillus coli communis to take on an aggressive penetrative action. If the condition be one of mucous catarrh, one or another result may happen—either the mucus is extruded or the cavity of the appendix becomes distended by it. Boracic acid may set up an inflammatory condition of the intestines, and thus, according to Mr. Williams, it is quite on the cards that it may be responsible for the above condition in that small and seemingly useless fragment of the bowel which is productive of so much activity among the surgeons.

News of the Week.

Examination for Hospital Internes, Panama Canal Service.—The United States Civil Service Commission announces an examination on July 12 and 13, 1905, at the usual places, to secure eligibles from which to make certification to fill vacancies in the position of hospital interne under the Isthmian Canal Commission on the Isthmus of Panama. As an insufficient number of eligibles resulted from the examination held on January 18, for this position, qualified persons are urged to enter this examination. Men only will be admitted to this examination. Each applicant for the Isthmian Canal Service will be required to submit to the examiner on the day he is examined, a photograph of himself, taken within three years, which will be filed with his examination papers as a means of identification in case he receives appointment. An unmounted photograph is preferred. The date, place, and kind of examination, the examination number, the competitor's name, and the year in which the photograph was taken should be indicated on the photograph. Age limit, 20 to 30 years on the date of examination; salary, $50 per month, with board and quarters, provided that if appointees are retained in the position of interne after one year they will be paid $125 per month. Only graduates of reputable medical schools having a three years' course will be admitted to the examination, which will extend over two days and will consist of the subjects mentioned below, with the relative weights indicated: 1. Letter-writing (the subject-matter on a topic relative to the practice of medicine), 5; 2. Anatomy and physiology (general questions on anatomy and physiology, and histological or minute anatomy), 15; 3. Chemistry, materia medica, and therapeutics (elementary questions in inorganic and organic chemistry; the physiological action and therapeutic uses and doses of drugs), 10; 4. Surgery and surgical pathology (general surgery, surgical diagnosis, the pathology of surgical diseases), 20; 5. General pathology and practice (the symptomatology, etiology, diagnosis, pathology, and treatment of disease), 25; 6. Bacteriology and hygiene (bacteriological methods, especially those relating to diagnosis; the application of hygienic methods and prophylaxis and treatment), 10; 7. Obstetrics and gynecology (the general practice of obstetrics; disease of women, their pathology, diagnosis, symptoms, and treatment, medical and surgical), 15. This examination is open to all citizens of the United States and also to aliens who comply with the requirements, provided that aliens appointed for service on the Isthmus of Panama shall not be eligible for appointment or transfer to any other branch of the public service. No person will be appointed for service on the Isthmus who is not physically sound and in good health. Persons appointed to positions under the Isthmian Canal Commission will be expected to proceed promptly to the Isthmus. Persons examined for positions under that Commission will not be eligible, as the result of such examination, to positions in the United States or Philippine services. Applicants should at once apply to the United States Civil Service Commission, Washington, D. C. No application will be accepted unless properly executed and filed with the Commission at Washington.

Looking for a Site for a Sanatorium.—The Health Commission of this city recently went to Orange County to inspect a proposed site for the new tuberculosis hospital which, it is said, he has been assured can be obtained in that county. Under the terms of the Bedell bill, which provides for the erection of a tuberculosis sanatorium by this city, the consent of the county in which the hospital is to be situated must be obtained before a site can be purchased. Several sites have been favorably considered, but in every instance the residents of the county have opposed bitterly the placing of the hospital among them. Sullivan County was the last to make a successful fight. It is said that the Orange County site under consideration is an ideal one in every respect and that there will be little or no opposition to the building of the hospital there.

A Threatened Cholera Outbreak in Russia.—There is some anxiety in St. Petersburg lest an epidemic of cholera add to the troubles of that unhappy country. A despatch from Sosnovice, Poland, reports that deaths are occurring daily there, and that three suspected cases are reported at Tula. The authorities of both these cities have ordered anti-cholera inoculations in the infected regions. At Harbin about 100 deaths occur daily from cholera and dysentery, and it is feared that the disease may spread thence along the Siberian railway into European Russia.

Claim Against the County for Mad Dog Bites.—Whether the county must pay damages for bites by mad dogs within its limits is a question now puzzling the commissioners of Hamilton County, Ohio. There is a statute in the Ohio code which allows persons bitten by mad dogs a sum of not more than $500, but until recently no one ever presented a claim of this kind. Two claims have now been presented from a woman and her mother, both of whom were bitten by the same dog on two different days, and both of whom went to the Chicago Pasteur Institute for treatment. One woman wants $201, and the other $191.

The Texas State Medical Association.—The annual meeting of this association was held at Houston, April 27-28, under the presidency of Dr. F. E. Daniel. The following officers were elected: *President,* Dr. J. Edward Gilcrest of Gainesville; *Vice-President,* Dr. B. Marvin Grace of Seguin; *Secretary,* Ira C. Chase of Fort Worth.

South Carolina Medical Society.—At the fifty-seventh annual meeting of this society, held in Greensville, under the presidency of Dr. Robert Wilson, Jr., in April, the following officers were elected: *President,* Dr. Davis Furman, Greenville; *Vice-Presidents,* Drs. Stewart W. Pryor, Chester, Crown W. Torrence, Union, and David B. Frontis, Ridge spring; *Secretary,* Dr. T. Prioleau Whaley, Charleston; *Treasurer,* Dr. Charles P. Atmar. The society will meet next year in Columbia, the third Wednesday in April.

American Association of Genitourinary Surgeons.—At the annual meeting of this society in Montreal, the following officers were elected: *President,* Dr. F. Tilden Brown of New York; *Vice-President,* Dr. Wm. K. Otis of New York; *Secretary,* Dr. John Van der Poel of New York; *Member of Council,* Dr. Hugh H. Young of Baltimore. Next place of meeting, New York City.

Medical College of Ohio.—The following changes have been made in the faculty of the Medical Department of the University of Cincinnati: Dr. F. Forchheimer was elected Dean, in the place of Dr. P. S. Conner, resigned. Dr. Joseph Ransohoff was made professor of surgery, Dr. H. J. Whitacre professor of principles of surgery, Dr. S. P. Kramer professor of surgical pathology.

North Carolina Medical Society.—At the annual meeting of this Society at Greensboro, May 23 to 25, the following officers were elected: *President,* Dr. Edward C. Register, Charlotte; *Vice-Presidents,*

Drs. L. B. McBrayer, Asheville, W. H. H. Cobb, Jr., Goldsboro, W. O. Spencer, Winston; *Secretary,* Dr. J. Howell Way, Waynesville. The next annual meeting will be held at Charlotte.

Commencement Exercises of Rush Medical College.—The annual commencement exercises of this institution were held in Mandel Hall, at the University of Chicago, June 16. Seventy-one students received the degree of M.D. The honors were: Fellowship in Pathology, Herman E. Wolf; Fellowship in Medicine, Ludwig M. Loeb; De Laskie Miller prize, Emmet James Howell. The commencement address was delivered by Dr. Ira Remsen, president of Johns Hopkins University.

Dr. James A. Egan of Springfield, Ill., secretary of the State Board of Health, has been appointed a member of a committee to inspect the Illinois State military schools.

Indiana Conference of Health Officers.—Under the auspices of the State Board of Health of Indiana, the annual conference of health officers was held at Indianapolis June 1, 2, and 3. Addresses were delivered by Drs. Seneca Egbert and Joseph McFarland of Philadelphia.

St. John's Guild Hospital Opened.—The twenty-fifth season of the Seaside Hospital, maintained at New Dorp, Staten Island, by St. John's Guild, has been opened. The hospital is equipped for the care of children needing prolonged fresh air treatment, and, though not a summer home, well children are received where circumstances are such that they cannot be cared for at home and some member of the family is in need of hospital care. Until the Floating Hospital begins its daily trips, patients for the Seaside Hospital will be met at the Staten Island ferry, foot of Whitehall street, by a nurse and orderly, and, after examination by an inspector from the Department of Health, will be conveyed to New Dorp by boats leaving Manhattan at 10 A. M. and 2.30 P. M. Persons who may know of sick children needing hospital treatment are invited to communicate with the general agent at 501 Fifth avenue.

McGill Commencement. — Convocation exercises marking the close of the seventy-sixth year of the medical faculty of McGill were held June 10, in the assembly hall of the Royal Victoria College. The year has been a notable one for the faculty of medicine in that it has marked the amalgamation with McGill of the medical faculty of Bishop's College, Lennoxville. A most important feature of the year has also been the action of the medical faculty of McGill in applying to the governors for fuller union with the university. The administration of the faculty will now be centered in the hands of the university in the same way as the administration of the other faculties, thus tending to the unification of McGill as a whole. Seventy-three candidates received their medical degrees.

International Prizes for Essays on Lead Poisoning.—The Internationales Arbeitsamt, in Basle, Switzerland, has offered twelve prizes, amounting in all to 27,000 marks for the best essays dealing with the various problems connected with the prevention of lead poisoning in the various industries in which this danger exists. Papers may be written in English, French, or German, and must be submitted before December 31, 1905. Information may be obtained by addressing "Das Internationales Arbeitssamt, Basle, Switzerland."

Dispensary Cures of Tuberculosis.—The number of cures of tuberculosis by home treatment under the direction of the Post Graduate Hospital Dispensary has now reached forty-five. The last five cases reported by Drs. T. W. Bickerton and D. M. Barstow, included a tailor, a clerk, a barber, a saleswoman, and an elevated railroad guard. All continued their work during the treatment, which lasted from two months to two years.

The German Association of Naturalists and Physicians will hold its seventy-seventh annual meeting this year at Meran from September 24 to 30. The work of the scientific branch of the congress will be distributed among fourteen, that of the medical branch among seventeen sections. At the general meetings addresses will be delivered by Professor Langley of Cambridge, on recent researches on the nervous system, and by Professor Correus of Leipzig, and Professor Heider of Innsbruck, on the laws of heredity.

Improving Health Conditions in New York.—According to the weekly report of the Health Department, the death rate of the city for the week ending June 17 was 16.77 per 1,000, as compared with 22.69 for the corresponding week last year. There were forty-two deaths from cerebrospinal meningitis, as compared with fifty-four for the corresponding week last year, and 120 deaths from pneumonia, against 139 for last year.

St. Vincent's Hospital.—At a recent meeting of the Medical Board of this hospital the following appointments and promotions were made: Dr. Edward L. Keyes, Jr., visiting surgeon; Drs. Charles F. Fitzgerald and William C. Lusk, assistant visiting surgeons; Dr. William M. Ford, acting assistant visiting surgeon; Drs. John J. Morrisey and Peter Murray, assistant visiting physicians.

A Türck Centenary.—The Laryngological Society of Vienna announces that a celebration will take place in Vienna, under its auspices, of the centennial of the foundation on a practical basis of clinical laryngoscopy by Türck. The laryngologists of the world will be asked to take part.

Medical Department of the University of Illinois.—The twenty-third annual commencement of the Chicago College of Physicians and Surgeons was held June 6. A class of 213 was graduated, and of this number there were thirteen women, four of whom appear on the honor list. The doctorate address was delivered by Rev. Wm. A. Quayle, and the degrees were conferred by Prof. T. J. Burrill, Vice-President of the University.

Dr. Frank P. Norbury of Jacksonville, Ill., has been elected Professor of Nervous and Mental Diseases in the Keokuk Medical College, Keokuk, Iowa.

Duplicate Degrees for Dr. Osler.—The Convocation of Oxford University proposes to confer on Dr. William Osler the degree of Doctor of Medicine.

Heavy Fine for a Quack.—A man who was convicted last week for the third time for practising medicine without being registered, was fined $500. He had maintained, according to the testimony, an institute for producing doctors for a fee of $50 (the process requiring only a few weeks), a massage establishment, and an office in which he gave ordinary medical treatment.

Dr. Charles E. Atwood, who has been connected with Bloomingdale for the past thirteen years as assistant physician, has resigned and will be succeeded by Dr. August Hoch, for about twelve years connected with the Psychological Laboratory at the McLean Hospital, at Waverly, Mass.

Dr. Eugene H. Porter, of New York City, the editor of the *North American Journal of Homeopathy,* has been appointed Commissioner of Health of the State of New York, to succeed Dr. Daniel Lewis, whose term of office has expired.

Dr. Fredric Griffith has been appointed a member of the International Peace Conference, to be held in Lucerne, Switzerland. Dr. Griffith attends as the accredited agent of the Pennsylvania State Society.

Explosion in the Presbyterian Hospital.—Through the bursting of a steampipe leading to the sterilizing plant of the main operating room, one of the machines in the Presbyterian Hospital in this city was wrecked recently, and the operative work for the afternoon had to be postponed.

New Private Hospital for San Francisco.—Drs. J. H. and W. F. Barbat, H. B. A. Kugeler, C. G. Kenyon, J. A. Black, E. LeR. Wemple, E. LeR. Wemple, Jr., and several others, are preparing to build a new private hospital at San Francisco, which it is said will cost more than $150,000, in addition to the cost of the ground, and surpass all other institutions of the kind on the Pacific Coast.

Dr. S. S. Bogle, County Physician of Sonoma county, California, has been elected health officer of the same county, to succeed the late Dr. M. M. Shearer.

A Kosher Butcher of San Francisco has been charged with committing an abomination, in that he sold embalmed meat to his people. It was found that he not only preserved the flesh with the aid of formaldehyde, but that he dipped it into coloring fluids in order to give it a fresh appearance.

International Tuberculosis Association.—It is reported from Berlin that the United States National Association for the Study and Prevention of Tuberculosis has joined the International Association, making twenty-one national societies that are members.

Madison County (Ill.) Medical Society.—At the annual meeting of the society these officers were elected: *President,* Dr. Hinchee of Moro; *Vice-President,* Dr. E. E. Lemen of Upper Alton; *Secretary,* Dr. F. T. Joesting of Alton; *Treasurer,* Dr. H. W. Davis.

Kentucky Anti-Tuberculosis Association.—The incorporators of the association have effected a permanent organization by electing the following officers: *President,* W. C. Nones; *Vice-President,* Dr. W. H. Ramsay; *Secretary,* George L. Sehon; *Treasurer,* Theodore Harris.

Wisconsin State Medical Society.—At the recent meeting of this society, held in La Crosse, Milwaukee was unanimously chosen as the place for the next meeting. The following officers were elected: *President,* Dr. J. H. Currens of Two Rivers; *First Vice-President,* Dr. A. W. Gray of Milwaukee; *Second Vice-President,* Dr. A. Gunderson of La Crosse; *Third Vice-President,* Dr. Wm. E. Fairchilds of Green Bay. The secretary and treasurer will be chosen at the annual meeting of the council, to be held in Milwaukee next January.

Maine State Medical Association.—At the annual session of this society, held in Portland, the following officers were elected: *President,* Dr. Randall D. Bibber of Bath; *First Vice-President,* Dr. Chas. D. Smith of Portland; *Second Vice-President,* Dr. Daniel W. Hayes of Henderson; *Treasurer,* Dr. Arthur C. Gilson of Portland; *Secretary,* Dr. Walter H. Tobie of Portland. The next meeting is to be held in Portland on the first Wednesday, Thursday, and Friday of June, 1906.

New England Eclectic Medical Association.—The following officers were elected at the Montpelier, Vt., meeting of this society: *President,* Dr. Frank Winchester Snell, Dennysville, Me.; *First Vice-President,* A. H. Flower, Boston; *Second Vice-President,* Chas. J. Percival, Boston; *Third Vice-President,* Amos E. Parlin, Barton Landing; *Secretary,* Sylvena A. Abbott, Taunton, Mass.; *Treasurer,* Frederick W. Abbott, Taunton, Mass. Portland, Me., was selected as the next place of meeting.

Arizona State Medical Association.—At the meeting of this association, held in Prescott, the following officers were elected: *President,* Dr. J. W. Coleman of Jerome; *First Vice-President,* Dr. A. W. Olcutt of Tucson; *Second Vice-President,* Dr. O. E. Plath of Phoenix; *Third Vice-President,* Dr. Early of Kingman; *Secretary,* Dr. J. W. Foss of Phoenix; *Treasurer,* Dr. R. F. Palmer of Roosevelt. Phoenix will be the next place of meeting.

Maine Homeopathic Medical Society.—The thirty-ninth annual meeting of this society was held in Portland, and the following officers were elected: Dr. E. F. Root, Salt Lake; *First Vice-President,* Dr. Samuel Worcester; *Second Vice-President,* Dr. R. J. Wasgatt; *Recording Secretary,* Dr. Cora M. Johnson; *Corresponding Secretary,* Dr. L. A. Brown; *Treasurer,* Dr. William S Thompson.

Utah State Medical Association.—The following officers have been elected for this society: *President,* Dr. E. F. Root, Salt Lake; *First VXice-President,* Dr. C. F. Osgood, Morgan; *Second Vice-President,* Dr. A. Raucher, South Cottonwood; *Treasurer,* Dr. J. N. Harrison, Salt Lake; *Secretary,* Dr. W. S. Ellerbeck, Salt Lake.

Worcester District of the Massachusetts Medical Society.—The following officers were elected for the coming year at the annual meeting of this society, held in Worcester: *President,* Dr. E. W. Norwood, Spencer; *Vice-President,* Dr. David Harrower, Worcester; *Secretary,* Dr. G. E. Emery, Worcester; *Treasurer,* Dr. George O. Ward, Worcester; *Orator,* Dr. L. F. Woodward, Worcester; *Committee on Funds,* Dr. H. M. Quinby, Worcester; Dr. S. B. Woodward, Worcester; Dr. O. H. Everett, Worcester; *Commissioner on Trials,* Dr. C. H. Perry, Worcester.

Middlesex East (Mass.) Medical Society.—At the annual meeting held at Stoneham, the following officers were elected for this society: *President,* Dr. Silas H. Parks, Reading; *Vice-President,* Dr. Harrison G. Blake, Woburn; *Secretary,* Dr. Corydon W. Harlow, Melrose Highlands; *Treasurer,* Dr. Charles Dutton, Wakefield.

Ohio State Medical Association.—At the annual meeting of this association at Columbus the following officers were elected: *President,* Dr. Thomas Charles Martin of Cleveland; *First Vice-President,* Dr. B. H. Lean, Lebanon; *Second Vice-President,* Dr. W. B. Hedges, Delaware; *Third Vice-President,* Dr. John A. Dickson, Ashtabula County; *Fourth Vice-President,* Dr. D. R. Silver, Sidney; *Councillors*: Second district, Dr. Horace Bonner, Dayton; Fifth district, Dr. Will E. Lower, Cleveland; Seventh district, Dr. J. C. M. Floyd, Steubenville. Canton was selected as the next place of meeting.

Louisiana State Medical Society.—At the last executive session of the meeting of this society, held in New Orleans, the following officers were elected: *President,* Dr. C. J. Ducate, Avoyelles; *Vice-President,* Dr. J. F. Oechsner, New Oorleans; *Second Vice-President,* Dr. J. J. Ayo, Lafourche; *Third Vice-President,* Dr. D. S. Sarter, Richland; *Secretary,* Dr. P. L. Thibaut, New Orleans; *Treasurer,* Dr. M. H. McGuire, New Orleans.

St. Ann's Foundling Asylum, St. Louis.—This institution is said to be the first of its kind founded in this country. The work was begun by the Sisters of

St. Vincent de Paul in 1852, and since that time over 18,000 abandoned infants have been cared for. The Sisters have just moved into a new building on Page and Union Boulevard, erected at a cost of $250,000.

Physicians' Club of Chicago.—At the annual meeting of this Club, recently held, Dr. Chas. L. Mix was elected *Secretary,* and Drs. Clarence A. Earle, Henry F. Lewis, and Arthur M. Corwin were elected *Directors.*

Marine Surgery.—One of the stewards on the White Star lined *Majestic,* who was making his first trip, became so seasick that his efforts caused an old hernia to become strangulated. The ship's surgeon, Dr. Francis, successfully performed a herniotomy, the ship being stopped during the time of the operation.

A New Hospital for San Francisco.—Plans are being completed for the building of a new City and County Hospital at San Francisco. One million dollars, it is claimed, will be expended upon it.

The Late Dr. John H. Hinton.—At a stated meeting of the Medical Association of the Greater City of New York, held June 12, 1905, a minute on the death of Dr. John H. Hinton was presented, after which the following resolutions were adopted:

Resolved, That by the death of Dr. John H. Hinton this Association has lost a distinguished and honored member.

Resolved, That we extend to the bereaved family our profound sympathy for them, in this, the time of their sorrow.

(Signed) R. E. Van Gieson, *Chairman;*
P. Brynberg Porter,
J. Blake White.

Obituary Notes.—Sylvanus S. Finkbiner died at Parkersford, Pa., on June 12, at the age of 61 years. He was graduated from Jefferson Medical College in the class of 1865.

Dr. David Denison Stewart died of appendicitis at Philadelphia on June 13, at the age of 46 years. He was graduated from Jefferson Medical College in the class of 1879. He was well known for his exposure, some fifteen years ago, of the use by bakers of lead chromate for the purpose of giving an attractive yellow color to cakes and from which a number of fatalities of obscure origin had occurred. He was an able clinician, of latter years more particularly in the field of diseases of the stomach and intestines. He occupied the chair in these subjects in the Philadelphia Polyclinic for a number of years and he was one of the physicians of the Episcopal Hospital. He was also at one time physician to St. Mary's Hospital and to St. Christopher's Hospital for Children. He was consulting physician to the Kensington Hospital for Women.

Dr. Matthew W. Donavin of Baltimore died June 4, after a lingering illness, at the age of 67 years. He was born in Shippensburg, Pa., and was graduated from the Medical Department of the University of Maryland in 1866.

Dr. Charles W. Bush, a native of Pennsylvania, who crossed the plains in an ox-wagon in 1849, died at his home in Los Angeles on May 9, where he had lived since 1861. Dr. Bush was elected State Senator in 1872 and served two terms. He was the author of the first medical practice bill drafted in California. He retired from active practice several years ago.

Dr. Edward L. Newhall of Lynn, Mass., died on June 12, at the age of 83 years. He was born in Lynn, and was graduated from the Harvard Medical School in the class of 1848. He retired from active practice several years ago.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

THE PARIS TRIP—CONCENTRATION OF MEDICAL TEACHING—LYMPHORRHAGES — HYPNOTICS IN INSOMNIA — MEDICAL COUNCIL—FEEBLE-MINDED.

London, June 2, 1905.

The visit to Paris seems to have been a marked success, for those who have returned are full of the delightful entertainments provided. Most of them say that our reception of our French confrères has been completely eclipsed by the return compliment. That is indeed no more than might have been expected, the French being masters in such arts with whom we cannot compete. The excursions provided, Vichy, Pau, Biarritz and others, were on a scale worthy of the great French Spas.

The amalgamation of the medical schools, or as it is sometimes expressed, the concentration of teaching, has long been a subject of discussion, and recent events have invested it with fresh interest. The pourparlers I mentioned are still going on, and perhaps a degree of concentration may be attained. Meantime it should not be forgotten that London is a big place, and what suits a good sized provincial town, may not be best for the metropolis. The larger schools have always considered that the competition of the smaller ones was unnecessary, but these latter being independent, were mostly ready to show their capabilities. With the reorganization of the London University the advocates of concentration have taken courage and declare unification is the "counsel of perfection." Such a glamour has fallen upon them that they see in the new medical institute of the university a prospect of complete success, and the supporters of the scheme number many who, at one time, were its opponents. Many difficulties will arise—some are already acute. For instance, financial. It has been said that the number of schools led to extravagant expenditure. But the University is actually asking for £375,000 to start its new institute for teaching the medical sciences. The cost of maintaining it, when established, is estimated at £25,000 annually. The teachers of anatomy and physiology are to have £10,500 per annum. The number of students is put at 500. The 11 schools educate more than double the number at much less cost—how much less is questioned. Mr. Morris, in his recent oration, estimated it at something like £16,000 a year. Clearly, the charge of extravagance ought not to be brought against the schools. With regard to anatomy and physiology, the further question arises as to whether it would not be injurious to separate the laboratories altogether from the hospitals for the sake of concentrating the professorial teaching in a single building. Men actively engaged in practising in the wards are perhaps the best teachers of these subjects.

"Lymphorrhages" is a name proposed by Dr. Farquhar Buzzard for small collections of cells resembling lymphocytes which he found scattered irregularly between the cells of a glandular organ—their general appearance suggesting to him that of capillary hemorrhages, except that the cells were not red blood corpuscles. A small, empty capillary vessel lined by a single layer of endothelium had been seen in the vicinity of some of these lymphorrhages. These collections he had found in a smaller or larger number of the muscles in 5 cases of myasthenia gravis, which he brought before the Pathological Society. In some of them a prolonged search was required before they were found. The ocular muscles had been most fruitful in result. The only other changes found in the muscles of these cases were that a few fibers had become swollen and rounded, more hyaline and granular, often showing a tendency to stain paler with eosin or fuchsin. Lymphorrhages had been found also in the liver, adrenals, thyroid, and heart muscle. In one instance a similar condition was met with in a posterior spinal root ganglion. In glandular organs these deposits are often unaccompanied by other changes, but in a few instances, where the collections are larger, the neighboring gland cells have undergone degeneration or destruction. The discovery of these changes in the muscles of five consecutive cases is suggestive of a definite morbid anatomy, though the absence of blood changes or any change in the general lymphatic system, leaves the origin of the deposits obscure. Much attention of late years has been directed to the state of the thymus in this disease, but the success has not been great, and it looks as if Dr. Buzzard may have struck a more fruitful field for research.

The use of hypnotics in insomnia has been freely discussed by the Medico-Psychological Society, and I think you will be interested in some of the opinions expressed. Dr. Robert Jones thought arteriosclerosis had often to do with cases in which great mental distress prevented sleep, and that alcohol helped sleep by dilating the arteries of the cerebral cortex. He had frequently used alcohol for this

purpose, and one extremely restless lunatic, who was not taking his food, had been given a meal and half a pint of stout through a tube twice a day with benefit. He admitted much may be said in favor of chemical restraint. He had found benefit follow 10 grains of calomel. He felt certain he had seen in asylum practice, the judicious use of a hypnotic avoid puerperal insanity.

Dr. Blandford recognized the necessity of considering the digestion, but he was sure he had seen patients prevented from drifting into insanity, by giving narcotics, and he constantly saw cases at an earlier stage than those in asylums. A restless patient put into a padded room was very likely to go to sleep and, of course, he would not give drugs in such case. He agreed with Dr. Jones about a full dose of calomel. Hyoscine was out of fashion, and seemed rather dangerous.

Dr. Mercier suggested that a wave of therapeutic nihilism had invaded the specialty. Patients were sent to asylums and then the cry was no restraint; but if they were to be treated by the open-door, why not outside? He saw no objection to chemical restraint, and mentioned cases of sudden breakdown cured at once by narcotics. He further laid stress on a full stomach as an aid to sleep.

Dr. T. D. Savill said before giving hypnotics the arterial tension ought to be tested, as nearly all these drugs acted on the arteries in some way.

Dr. H. Corner said he rarely gave hypnotics without regretting it. About 90 per cent. of the cases could very well be treated without them, by means of mechanical and food aids, and the watching and care of a good nurse.

The General Medical Council continued its sittings through the week, but not much more than I have reported will specially interest your readers. A good deal of its business consisted in accepting the reports of committees, and the unwieldy size of the council for its work necessarily leads to legislation by such devolution. It was remitted to the examination committee to prepare for the May session next year a report on the whole cycle of visitations and inspections of the final examinations. The report of the Dental Committee occupied much attention, and various recommendations as to dental examinations and diplomas were agreed to. The dentists indeed seem to have set the council an example of efficiency in the administration of the acts.

It was proposed by Mr. Brown, and seconded by Mr. Jackson, but declined, that the fees for attendance at the council be reduced. It was remitted to the Finance and Executive Committees to consider whether a small fee might not be charged for registration of students. The President had suggested that a fee of 5 shillings would cover the expense of the student's registration.

The subject of increasing the number of direct representatives was again brought up by Mr. Brown, who based his argument this time on the increase of the members of the profession. Mr. Jackson seconded and Sir V. Horsley said the intention of the Act evidently was that the profession should be fully represented. Dr. Little thought the council already too large, and work would be better done by smaller numbers (an opinion which coincided with that of all observers of the council's doings).

Dr. Moore did not like the idea that those who represented the universities and corporations were not also representatives of the profession. He should have learned by this time that the profession utterly repudiates the notion that it is represented by those who are merely sent to the council by the small governing bodies of the corporations.

No reform or enlargement of the council will do good until the formation of the corporations is extended to all who hold their diplomas. Then the profession would be represented in reality as well as the several licensing authorities.

Sir J. Crichton-Browne gave evidence before the Royal Commission on the care of the feeble-minded, and some of his statements will not be generally accepted. He estimated that 30 per cent. of the population are underfed, badly clothed, and living in unsanitary conditions, things which conduce to mental deterioration. He thought the effect of intemperance had been exaggerated and not more than 15 per cent. of idiocy was the result of parental alcoholism, though others estimate this evil at more than double that figure. He blamed more the proprietary foods so often substituted for natural feeding. Babies looking plump were often pale, flabby, and subject to rickets through artificial feeding. They were in reality partially starved just when the brain was growing.

He did not know a case benefited by a stay in a home for dipsomaniacs, and in some of these retreats he believed drinking went on and the idle loafing life was certainly demoralizing. The best results were obtained by residing in a doctor's house—always provided he were the right sort of doctor.

He suggested that weak-minded people who had lived in special schools should, on leaving, be sent to a house of observation for a time. Criminals, too, after a sojourn in prison, should be sent to an institution for observation. One doctor of a jail had stated that a third of the prisoners showed signs of weak-mindedness.

OUR BERLIN LETTER

GERMAN SURGICAL CONGRESS—BLOOD STASIS IN INFLAMMATION—APPENDICITIS—RENAL TUBERCULOSIS—TESTS OF RENAL FUNCTION—POST-OPERATIVE PNEUMONIA—TREATMENT OF FRACTURED PATELLA.

BERLIN, May 24, 1905.

It was a difficult matter for the visitors to the Surgeons' Congress and the Röntgen Congress which followed, to hear all of the papers which were read before the illustrious society, but the effort was richly rewarded.

This was the thirty-fourth meeting of the German Surgical Congress, and was held from April 26 to 29. It was presided over by Krönlein of Zurich. For the first time a plan was introduced of having one or two papers read by noted men who have done original work along the line which was made the special topic of the day. This was a very interesting feature. As it is impossible to give extended accounts of all of these papers in one letter, I shall restrict myself to a few of the chief points.

Bier of Bonn presented a paper on a "Method of Treating Acute Inflammatory Affections by Means of Blood Stasis." He demonstrated his method by exhibiting a number of cases which he intended to treat during the Congress. Be believes that recovery is accelerated by means of increasing the inflammation by the afflux of blood. He brings this about by compression exerted by a bandage or by suction tubes. The latter are very practicable in cases of panaritium and mastitis. The soft rubber bandage must be employed from ten to twenty-two hours. Abscesses should be opened. Pain stops immediately after the application of the bandage. After removal of the bandage, the extremity is suspended for two hours after which the compression can be repeated. Phlegmons, joint suppuration, mastoiditis, tendovaginitis, and purulent affections are cured in a very short time.

The perityphlitis question came in for a great deal of discussion. Körte of Berlin read the introductory paper on "The Favorable Time for Operative Interference in Inflammation of the Appendix." Koerte has changed his former views and now always prefers early operation. His experience in 137 cases has led him to adopt this view. He operates within the first forty-eight hours of onset in every case. Later he may open abscesses, but removes the appendix only after the disappearance of every inflammatory symptom. By this method he avoids many complications such as oöphoritis, and also the necessity of an interval operation which still shows a mortality of 1 per cent. Of the same opinion on this subject were Kümmel of Hamburg, Rotter of Berlin, Payr of Graz, Riese of Berlin, König of Altona, and Hochenegg of Vienna. Sonnenburg of Berlin and Roux of Lausanne alone preferred the interval operation. Sonnenburg distinguishes between two great groups—the early cases which at once show diffusion of the inflammation and which should be operated on immediately, and the simpler cases in which the inflammation is limited to the appendix, or in which at least the left side of the abdomen is not affected. and which do not require early operation, because in most of these cases spontaneous recovery takes place. According to Körte and other speakers, the leucocyte count does not offer any certainty in diagnosis, or any other advantage.

Another subject of great interest came up for discussion, and was considered by the most eminent authorities. This was renal tuberculosis. Rovsing of Copenhagen and Israel of Berlin, read the introductory papers: "Concerning the Indications and Results of Special Kidney Extirpation in Renal Tuberculosis" and "The Influence of the Functional Diagnostic Methods on the Results of Nephrectomy for Renal Tuberculosis." Rovsing warns against placing confidence in the functional diagnostic methods. The measurement of nitrogen, the phloridzin test, and cryoscopy give misleading results. He has operated in cases in which, to judge from these criteria, operation was contraindicated, and with good results. Two patients who, according to these signs, were considered well, died from renal insufficiency. Rovsing believes that his good results are due to the following routine: Regular measurement of nitrogen and catheterization of the ureters and exact examination of the urine which allow one to judge of the condition of both kidneys. When the urine of the healthy kidney contains albumin without tubercle bacilli or other elements, the alteration is only toxic and suggests the extirpation of the other kidney. When catheterization of the ureter is impossible, he explores the kidneys by means of a double lumbar incision. The urine segregator does not always separate both urines perfectly. Israel condemns the func-

tional diagnostic methods for the reason that the cryoscopic results are untrustworthy. He observed the normal freezing point in urine from a solitary kidney which was already destroyed to a great extent. The phloridzin test is superfluous because in every case it is possible to determine by other methods which of the two kidneys is the more seriously affected. All of these methods must yield false results because they measure only the work performed in a short time, and not the function itself. It is only when the kidney is forced to work up to the limit, for example, after the ingestion of large quantities of water, that its condition can be determined. Even the Luys method employed according to this point of view has been found wanting. The question was raised how Casper had been able to present such good results obtained by men who made use of functional diagnostic methods, as compared with the less favorable results of the surgeons who did not employ them. This fact is due simply to difference in statistics. Casper has shown on the one hand only the older operators who had not had so much practice, and on the other hand, those who had had large experience. Israel's results have become better since 1901, and better (7 per cent.) than those of Kümmel (8 per cent.), when he took out of his statistics malignant tumors as Kümmel did. The real cause of the improvement in the mortality rate depends upon the indications in the cases. Now the earlier cases are operated on contrary to the custom of former times. Early operation does away with a number of cases in which both kidneys are affected; it prevents the development of cardiac trouble which occurs in cases of longer standing, and finally, it is easier to perform.

In opposition to the views of these two speakers, were those of Kümmel and Casper who advocated the use of cryoscopy and the phloridzin test. Casper admitted that his method gives different results at different times, depending upon the quantity of urine secreted. He has improved his method. He now gives from 50 to 100 grammes of milk and makes an examination two hours later, when he injects 1 centigramme of phloridzin. By this method he has been enabled to determine the presence of sugar in one hundred cases.

Kümmel believes that when the freezing point is normal, there is sufficient kidney tissue to functionate. After using cryoscopy in one thousand cases he has had no cause of regret in a single case. He has never had a death from renal insufficiency. He believes that the unsatisfactory results of other workers comes from their imperfect technique. In these cases several examinations should be performed. He believes that nephrectomy should never be performed when the freezing point exceeds 0.6° C. Barth of Danzig, and Strauss of Frankfort, preferred the functional methods which they thought made the operator more certain and also permitted of an early diagnosis of tumors. Völker of Heidelberg, recommended his indigo-carmine method, and Frank of Berlin and Kocher of Berne have had great succes with the segregator of Luys in cases in which it was impossible to catheterize the ureter. By this method, too, is avoided the polyuria caused by the catheter. After the admirable papers of Israel and Rovsing, it is most probable that confidence in functional methods will be diminished. However, after hearing the decided opinions of Casper and Kümmel, still further investigations must be made along these lines before the final judgment is given.

Kelling of Dresden read a most interesting and important paper on "Post-operative Pneumonia." According to Kelling, pneumonias are more frequent after operations in the upper parts of the abdomen. They are caused by aspiration and are favored by the more difficult expiration and by the pains which prevent the patient from indulging in deep respiration. The embolic processes which take place in the blood or lymphatic vessels are not so important in the development of pneumonia. Kümmel of Hamburg had better results after the employment of the scopolamin-morphine narcosis. Franke of Braunschweig, and Kausch of Breslau, reported results contradictory to those of Kümmel, however. According to the opinions of twenty-three speakers, including Häusler, König, Rehn, Rotter, and Friedrich, there are still many facts to be explained in regard to the development of pneumonia. Krönlein of Zurich, scarcely ever met with post-operative pneumonia.

The last important paper was read by Thiem of Cottbus, on "The Results of Bloodless Treatment and of Operation in Subcutaneous Transverse Fracture of the Patella." All of the speakers, and they were the best surgeons, agreed that the cases should be operated on as soon as possible when it was impossible to separate the broken parts. According to Thiem's statistics, the patients who were operated upon suffered less from unhappy effects of the fracture than those who were not operated upon. The best argument is the fact that the operatives' insurance societies have to pay 1,960 marks for every man who is operated upon, and 3,000 marks for every man who is not operated upon. The elder König of Berlin advised operation in all cases without exception.

OUR LETTER FROM THE PHILIPPINES.

(From Our Regular Correspondent.)

ELECTRIC CARS IN MANILA—NEW PRIVATE HOSPITALS—IMPROVEMENTS IN THE CIVIL HOSPITAL—SMALLPOX AT SHANGHAI—RELAXING QUARANTINE RESTRICTIONS—A NEW COMMISSIONER OF PUBLIC HEALTH.

Manila P. I., April 29, 1905.

THE opening of the Manila electric street car system, which took place April 10, was a most agreeable surprise in many respects. It was freely predicted that the fast moving cars, operating upon the narrow streets of this ancient city, among a population that since time immemorial has spent much of its time in the streets, and which has not been accustomed to move in other than a leisurely manner, would certainly result in many accidents until the danger was fully appreciated. So firm was this belief that an operating room and hospital facilities were hastily prepared for the purpose of taking care of the persons whom it was anticipated would be injured. The cars have been running now for more than two weeks and only a few accidents of the most minor character have been reported. This is merely another instance which goes to show how easily the Filipino people accommodate themselves to modern innovations.

The hospital facilities, the lack of which has been so keenly felt by the American population and the medical profession of Manila, will shortly be provided for, at least to a limited extent. Archbishop Harty, of the Catholic Church, and Bishop Brent, of the Episcopal Church, are each about to start a hospital, to be conducted by the respective organizations which they represent. The large stone building situated in the walled city on Calle Palacio, which was formerly used as the headquarters of the provost marshal general, is being renovated, new plumbing is being installed, and equipment purchased for the same. It is expected that it will be ready for the reception of patients within the next few weeks. The hospital is to be under the direct supervision of the Sisters of St. Paul. The principal medical officer will be Dr. J. R. McDill, the former president of the Philippine Islands Medical Association and of the Manila Medical Society. It is planned to have an out-patient department, which will include among other dispensaries a free dental clinic, in charge of Louis Ottofy, D.D.S. The latter believes that there are certain matters in connection with the eruption of teeth which have a direct bearing upon the high infant mortality which occurs in Manila, and he expects to make an exhaustive study of this matter with the material which presents itself at the clinic. The hospital is unfortunately located, in that it is in a closely built-up section of the city, where the streets are narrow and the free entrance of light and air will be hindered; but a hospital which is not ideal is obviously so much better than no hospital that it would be idle to discuss this matter.

Bishop Brent has just returned from the United States with sufficient funds to start a hospital of modest proportions. It is his intention to build a new structure on a site suitable for the purpose. His church has for some years past conducted a free dispensary on Calle Magdalena, where many hundred indigent natives have received relief. For the new hospital much of the equipment has already arrived, but it will probably be some months yet before the building will be ready to receive it.

It is also hoped that the Civil Hospital, which is operated by the government for the benefit of the civil employes, will soon be removed to larger and more suitable buildings. It is believed that negotiations are now under way between the army and the insular government with the view of the former vacating the buildings at present occupied by the First Reserve Hospital. The capacity of the latter is over three hundred beds. The plan is to have the army remove all of its sick in the First Reserve Hospital to the new hospital, now being constructed at Fort William McKinley. The latter is about five miles from Manila. With all of the foregoing contemplated improvements, Manila will have advanced a long step in the direction of relieving distress, not only among the white population, but among the natives as well.

With the abatement of the cold weather at Shanghai, there has been a decided improvement in the smallpox situation at that port. The number of cases of smallpox which have occurred among the crews of vessels which call at Shanghai has undergone a marked diminution, and the restrictions placed upon commerce from that port have, to a great extent, been removed.

In view of the large number of cases of plague occurring in India, it is most satisfactory to observe that there have been less cases in Manila this year than last. It is expected, however, that there will be an increase during the months of May and June, which are the months of the year during which the greatest number of cases have occurred in the past.

The sanitary situation in the islands has improved so much that the quarantine authorities have removed many of the restrictions which have heretofore been placed upon interisland commerce. Vessels are now only required to await quarantine inspection at the ports of Manila, Iloilo, and Cebu, and this is only maintained with the hope of improving the mechanical cleanliness of vessels. After May 15 bills of health will no longer be required of interisland vessels.

Major E. C. Carter sailed for the United States to-day. He was succeeded as Commissioner of Public Health for the Philippine Islands by Dr. Victor G. Heiser, of the U. S. Public Health and Marine Hospital Service.

A CASE OF BRADYCARDIA.

To the Editor of the Medical Record:

Sir: It has recently occurred to me that I should finish the history of a case of bradycardia reported in your columns in the issue of November 21, 1903. My patient steadily improved from the time of my report, his pulse reaching 65 and his strength increasing very decidedly, so much so that he could walk several blocks, but notwithstanding these gains he developed a peculiar fear of being alone, wanting some one always to be up with him if he awoke at night, and although his head seemed to be perfectly clear for business, he would not let his assistant discuss any details of his business with him. In fact, he tried the patience of his family to the utmost in keeping him in good humor, and could not bear to have his old friends call on him. From time to time I had to decrease the small dose of caffeine that at first seemed to make him more comfortable, because it made him too wakeful. In the same way the nitroglycerin made his heart pump so that I had to stop that, and finally the only medication he would tolerate was ⅛-grain doses of morphine. This drug seemed really to accelerate his heart action and quiet the almost insane fear that he had of dying while asleep of heart failure, this idea really making his life a burden to himself and his family. He still would have an occasional slight epileptiform seizure, these being worse and usually brought on when he was worried or tired.

On January 1, 1904, he felt well enough to superintend the making out of a complicated yearly report of his insurance business, and expressed himself as feeling remarkably well, and yet, to my alarm, I found his pulse 18 per minute. A week later he ate an indigestible supper and afterward sent for me. I found his pulse 10 to 12 per minute. He had had several epileptic seizures, some of which his wife assured me involved the whole body. He had several while I was with him which were milder, and only affected his head. After each one of these seizures he would thrust his fingers down his throat and attempt to vomit, not from nausea, he told me, but to remove something he felt in his throat and which something he felt brought on the attacks. There was no paralysis of the soft palate or vocal cords. Again the fear of sudden death became an unpleasant feature of his case, and at the same time he seemed to want to die, and, being of an intense religious nature, prayed to be released from his sufferings by death.

His condition grew gradually worse, and he finally died in an unusually severe convulsion on January 19. His pulse during the last week of his life never being over 10 per minute. His mind was clear to the last. Unfortunately, I never saw him in an unusually severe convulsion, but several observers assured me that these severe ones always brought on rigidity of the legs and arms, as well as the head, but he never frothed at the mouth or uttered a cry.

L. E. Norfleet, M.D.

Tarboro, N. C.

Lichen Spinulosus.—According to Adamson (*British Journal of Dermatology*) this is an affection of the skin occurring in children, usually boys, which is characterized by the appearance of fine filiform spines arranged in groups, more or less symmetrically distributed over trunk and limbs The filiform spines arise from pilosebaceous follicles, the mouths of which are slightly raised to form pin-head sized papules, either of the normal color of the skin or slightly red. They are unaccompanied by itching or other subjective sensations, and there is little or no disturbance of the general health. Histologically the lesions show a hyperkeratosis of the follicle, perifollicular inflammation being absent or slight. Lewandowsky (*Archiv für Dermatologie und Syphilis*) writes upon the same subject, but finds the affection a follicular one of inflammatory nature, with secondary parakeratosis or parahyperkeratosis. The case he describes showed inflammatory papules with a tendency to pustulation two or three weeks before the formation of spines which is not in accord with English observations of the affection as described by Adamson. The diagnosis is to be made from lichen planus, lichen scrofulosorum, pityriasis rubra pilaris, keratosis follicularis contagiosa, and possibly Darier's disease.

Progress of Medical Science.

Boston Medical and Surgical Journal, June 15, 1905.

Hypochlorization Method in the Treatment of Epilepsy.—Arthur Morton says the salt-poor diet has been in use at the Massachusetts Hospital for Epileptics for several years. It consists in the substitution of sodium bromide for sodium chloride in the patients' food. The claim is made that the bromide salt is rapidly absorbed and becomes a part of the body tissue when administered in this way. It is also stated that when the bromide is given in this way, only about one-half the usual quantity is needed to produce the sedative effect. From a study of the results obtained at the hospital mentioned, the author formulates the following conclusions: The hypochlorization method controls the convulsions, requiring only about one-half the amount of bromide usually given. It has little or no effect on the general nutrition of the patient. It is apt to cause constipation. It does not furnish enough salt to satisfy the patients' craving. It may be used with success with intelligent patients. It is practically useless in the middle grade of epileptics, as they have neither the desire nor the will power to carry it out properly. A modified salt-poor diet, in which about equal parts of sodium chloride and sodium bromide are used by the food may be employed to advantage with idiotic and demented patients if their diet can be controlled absolutely. Bromism is comparatively rare.

New York Medical Journal, June 17, 1905.

Observations on the Diagnosis and Treatment of Herpes Zoster.—The treatment of this form of skin disease is summarized by D. M. O. Robinson as follows: Rest, attention to the general nutrition of the body, the combating of the microbes, the application of cold over the affected ganglia, a coal tar preparation for the toxemia, and codeine and bromide of potassium for pain not controlled by the antipyrin. Local treatment consists in aseptic and antiseptic measures. If the case is seen at a very early stage, the affected area can be disinfected in the usual manner by soap and alcohol and then painted with flexible collodion—and when convenient an antiseptic gauze applied. If seen later, when vesicles are changing in color, an ointment of boric acid and bismuth subnitrate, and avoidance of soap and water meet the indications. Later ichthyol can be added to the ointment, or an antiparasitic preparation, as the ammoniated chloride of mercury ointment with rose ointment, to which bismuth may be added, and also ichthyol. For the persistent neuralgias following zoster, anodynes and the faradic current or *x*-ray may be of some curative value, but on account of probable structural changes in the nerves and connective tissue of the ganglia, the condition is very rebellious to usual methods of treatment for neuralgia. Tonics, such as phosphide of zinc, and alteratives, such as arsenic, are also recommended.

Fibroid Tumors of the Uterus; Their Surgical Treatment.—The conclusions presented by F. H. Martin are based (1) upon an analysis of the last 200 consecutive cases, operated on by him; (2) on the analysis of 1,188 cases, previously reported by C. P. Noble, and (3) on knowledge gained by the different forms of less radical operative procedures and on the non-operative methods of treatment employed by himself during a period of over eighteen years in caring for more than four hundred cases not submitted to radical operation. The conclusions are as follows: (1) The routine treatment for fibroids of the uterus, presenting symptoms, in women under 45 years of age should be supravaginal hysterectomy, except as hereinafter stated. The exception to this rule should be (*a*) in subperitoneal tumors, either pedunculated or not, in which only one or more distinct developments exist which do not materially increase the size of the uterus proper and the area of its endometrium, when myomectomies may be resorted to; (*b*) in fibroids which present excessive hemorrhagic tendencies, in which hemoglobin is reduced below 25 per cent., or in which serious vascular cardiac or kidney complications exist which greatly increase the risk of the operation, when a preliminary operation of vaginal ligation of the uterine arteries should be resorted to; (*c*) in cases where a radical operation will not be accepted, a curettage and vaginal ligation of the uterine arteries may be resorted to, or, if no operation at all will be accepted, general tonics, ergotin in tonic doses, and galvanism scientifically applied may be depended upon to relieve the patient materially, and occasionally tide them over the menopause to a complete symptomatic cure. (2) The treatment for large, complicated tumors without regard to age, or large apparently uncomplicated tumors in which symptoms of hemorrhage or pressure exist, should be supravaginal hysterectomy. (3) Tumors of medium size apparently uncomplicated in women over 45 years of age may be managed by one of the less radical forms of treat-

ment, as, (*a*) when the tumors are of the symmetrical development type, enlarging uniformly the uterus, and the principal symptom is an exaggerated menstrual flow, the cases may almost invariably be relieved by galvanism and tided over the menopause; or (*b*) if the growth is of the irregular type which has distorted more or less the uterine cavity, the case should be submitted to dilatation, finger exploration, curettement, and, if considerable flowing is a symptom, vaginal ligation of the uterine arteries, with the idea of obtaining a symptomatic cure over the menopause. (4) The extremely small class of tumors coming under the head of "inoperable" cases must be managed on general principles—rest in bed, general tonics, treatment of the cardiovascular and kidney complications when they exist, curetting and irrigating for septic endometritis, electricity for pain and hemorrhage, ligation of the uterine blood supply if practicable for intractable hemorrhage, and vaginal incision of impacted cysts or pus accumulations.

The Medical News, June 17, 1905.

The Value of Lumbar Puncture; with Particular Reference to the Diagnosis of Tuberculous Meningitis.—The paper of E. P. Bernstein is based upon the results of examination of 265 cerebrospinal fluids received at a hospital laboratory. Of this number 46 were specimens of inflammatory fluids, 40 of tuberculous fluids. In 84 meningococcus cases, the organism was found in all but 14, streptococci were found in a series of 9 cases five times, staphylococci twice, while two were negative, while the pneumococcus was found in each of a series of 3. The author has never been able to demonstrate the presence of glucose in the fluid in any stage of tuberculous meningitis, although Comba has declared that it is found in small amounts at the onset but is absent toward the end. Bernstein attaches the greatest value to the cytological examination of the fluid. The centrifuge must be used and spreadings made from the sediment. His elaborate tables give full details of each case in this respect. In a general way, a mononuclear leucocytosis goes with a tuberculous, and a polynuclear leucocytosis with a purulent meningitis, but no absolutely hard and fast lines can be laid down. Cryoscopy is of no value. Positive diagnosis can be made only from the bacteriological findings. The diplococcus intracellularis meningitidis was found most frequently in the author's studies, while the bacillus tuberculosis was next in frequency. He describes his technical methods in full. In regard to prognosis in tuberculous meningitis, he finds only four apparently authentic non-fatal cases on record.

The Carbohydrate Reactions of the Paratyphoid or Paracolon Group.—From the study of a series of bacterial cultures, W. W. Ford submits the following scheme of the various organisms found in the bowel from B. alcaligines to B. coli: Type I.—Ferments no carbohydrates. Represented by bacillus fecalis alcaligenes Petruschky. Type II.—Ferments the monosaccharids, dextrose, galactose, levulose, mannose, and the polysaccharid maltose. Represented by a number of cultures isolated by the writer from the contents of the normal intestine. Type III.—Ferments the monosaccharids, dextrose, galactose, levulose, mannose, the polysaccharids, maltose and rhamnose, the alcohols, mannite and dulcit. Represented by the bacillus of hog cholera, all cultures of which agree in their fermentative reactions. Type IV.—Ferments the monasaccharids, dextrose, galactose, levulose, mannose; the polysaccharids, rhamnose, maltose, and arabinose; the alcohols, mannite and dulcit. Represented by bacillus typhi murium, bacillus paratyphoid Müller (Schottmüller), bacillus paracolon Gwyn, bacillus paracolon Olsen (Howard), bacillus paracolon Badach (Johnson), bacillus paracolon Milefsky (Johnson). Type V.—Ferments the monosaccharids, dextrose, levulose, galactose, mannose; the polysaccharids, maltose, rhamnose, arabinose, xylose, the alcohols, dulcite and mannite. Represented by bacillus enteritidis Gärtner, bacillus cattle disease Möhler, bacillus rat plague Rosenau, bacillus septicus murinus, bacillus of guinea-pig disease Carter, bacillus of swine dysentery Theobald Smith, bacillus icteroides Saranelli, bacillus icteroides Pasteur Institute, bacillus paracolon Cushing, bacillus paracolon Strong, bacillus paracolon Buxton, bacillus paratyphoid Hunnamann (Schottmüller), bacillus paratyphoid Kurd. Type VI.—Ferments the monosaccharids dextrose, levulose, galactose, mannose; polysaccharids, saccharose, lactose, maltose, xylose, arabinose, rhamnose, melitose, raffinose, melibiose; alcohols, dulcit and mannite. Represented by bacillus coli.

American Medicine, June 17, 1905.

Relations of Public Health to Other Sciences.—William T. Sidgwick traces the development and progress of public health science and allied sciences from the eighteenth century down to the present time. He divides public health science as it is to-day into a consideration of (1) epidemiology; (2) sanitation of the environment; and (3) immunization of the human mechanism. Medical men must always participate in the management of public health science in connection, particularly, with the control of epidemics and in those forms of preventive medicine which have to do with vaccines, serums, and other means of modifying the vital resistance of the human body. But as regards the care and control of the environment, medical knowledge is not indispensable, and, therefore, the entrance of the engineer and the sanitary expert upon the field is to-day a conspicuous, and probably a wholesome fact.

Knee Injuries and How to Manage Them.—De Forest Willard says sprains of the knee are often followed by long continued results from the fact that ligamentous, tendinous, or fascial structures are torn. Permanent disability and weakness are common. An early diagnosis of the existence of such tear, or of fracture, or of dislocation of cartilages or of loose bodies, is essential. The Röntgen ray may assist. Rest, complete or partial, is the initial element of treatment. Heat and cold are the most powerful abortives of synovial inflammation. Partial fixation by adhesive plaster strapping, or fixation by plaster-of-paris or other solid splint, with the use of crutches, is helpful. The limitation of the period of rest is, however, most important. As soon as the inflammatory signs have subsided, massage and voluntary movements are important lest chronic tenderness of the joint be induced. Serous effusion is to be removed by compression, tapping, or incision. Blood clots should be removed. Displaced semilunar cartilages should be replaced by manipulation and recurrence avoided by an apparatus limiting motion. Upon recurrence of the injury, the cartilage should be stitched in place or removed. Loose bodies in the joint should be removed, when discovered. Sensitive or hysterical joints are induced by too long continuance of rest. These can only be cured by involuntary and voluntary movements, which should usually be preceded by anesthesia. Fibrous ankylosis can be overcome by forcible and cautious movements, with persistent massage, dry heat, manipulations, etc.

Tropical Anemia.—M. J. Rosenau gives his practical experience with the anemias found in the tropics. The causes of this condition are mostly uncinariasis and malaria. Kala-azar and other causes are also discussed. The clinical diagnosis is considered; but the importance of microscopical methods in recognizing hookworm eggs in the feces and the malarial parasites in the blood is strongly emphasized. The best methods of accurate diagnosis are stated. The treatment, prophylaxis, and economic importance of the diseases are considered.

Encephalitis and Other Nervous Diseases Complicating Scarlet Fever.—John H. W. Rhein reports the results of a pathological study of the brain taken from a patient who died of scarlet fever. While there were no clinical manifestations of meningeal irritation, the miscroscopic study of the brain showed the presence of a moderate degree of infiltration of the pia, and the presence of a few subpial hemorrhages, and in the cortex of the brain a moderate degree of distention of the perivascular spaces was observed. Studies made to discover miscroorganisms were not successful. The literature of the subject is carefully covered, and the following conclusions made. Hemiplegia and peripheral neuritis are the most common complications of scarlatina. More rarely scarlatina may be followed by paraplegia, optic neuritis, amaurosis, tetany, pseudoataxia, neuralgia, epilepsy, disseminated sclerosis. Friedreich's ataxia, chorea, hydrocephalus, meningitis, and disordered mental states. The prognosis is good excepting for hemiplegia and imbecility, if those rare organic cases are excluded such as Friedreich's ataxia, disseminated sclerosis, and epilepsy. The postmortem findings consist of thrombosi, embolism, small cerebral hemorrhages, abscess of the brain, congestion of the brain and meninges, and finally, meningitis and encephalitis.

Journal of the American Medical Association, June 17, 1905.

The Aortic and Mitral Valves.—John Homans and J. Burrage publish the results of their studies in the normal and pathologic histology of the aortic and mitral valves. They studied especially the normal structure and the variations of these bodies, their degenerative lesions with the relations of these to acute infections. After describing their technic and reviewing the literature which, they remark, is not full or accurate on this subject, the authors report their own findings in detail which were disappointing, in that they failed to find the expected relations between the degenerative lesions of the valves and acute infections. They can only conclude, they say, from their observations that mucoid and fatty degeneration of the valves do not apparently predispose to infection; that "benign thickenings" likewise do not, though it is hard in the case of the mitral valve to tell whether a thickening is benign or due to repeated acute attacks; that the thickenings in mitral valves when infected are better repaired than those of aortic valves; and that acute toxemias do not cause what they can recognize as degenerations predisposing to infection.

Turning in Organic Hemiplegia.—R. Pemberton has examined thirty-six cases of organic hemiplegia with special reference to the direction of turning in walking, to test Kidd's conclusion that if the patient turns to the affected side, an organic lesion is present. He found that only about two-thirds of the cases turned to the affected side; of the remainder about half turned to the sound side and the remainder turned indifferently to either side. Much depends on the degree of paralysis or deformity, according to Pemberton. If there is marked foot-drop and contracture of the affected limb, requiring it to be swung in a wide circle, the well leg will be the pivot. If the deformity is not so great and it is not necessary to swing the leg around, or it is difficult to do so, the affected leg may be the pivot. There may also be intermediate condition in which either limb can be used. He therefore considers Kidd's conclusion not universally applicable and not so reliable a test for organic involvement in hemiplegia.

The Prevention of Shock.—Assuming that surgical shock is due to the functional impairment or even exhaustion of the vasomotor centers through afferent impulses set up by trauma, exposure, etc., G. W. Crile discusses the means of its prevention, as well as that of hemorrhage, in various surgical procedures. Aside from the impulses mentioned, there are a number of important accessory causes to be reckoned with, he states, including psychic emotions such as fear, hemorrhage, cold, acute and chronic infections, anemia, cachexia, etc., and age and sex. One or more of these is met with in every case. Crile summarizes his views as follows: "Every tissue and organ has a more or less individual shock-producing value and must be individually considered. The amount of shock produced by a given trauma varies according to the amount and special quality of its nerve supply and the number and intensity of the afferent impulses originated by the injury or operation. Cocaine or eucaine may wholly 'block' these shock-producing impulses. When one or more of the accessory causes of shock are present the highest possible tax is laid on the surgical judgment of the operator. A precise technique offering a minimum of exposure and trauma, grafted on a comprehensive grasp of all the factors entering into the operative consideration, are the ideals for which we must strive."

Treatment of Middle Ear Disease.—A. E. Bulson, Jr., thinks that the prophylaxis of middle ear disease is too often neglected. Every slight earache should be looked after, constitutional conditions be attended to and proper treatment be given to conditions of the nose and throat. Opiates mask symptoms and should not be used for pain; dry heat will usually suffice. As the pain is due to pressure from congestion, the essential treatment is depletion, and this may be accomplished by catharsis, leeching, the application of carbolic acid and glycerin to the membrana tympani for its osmotic effect, or by direct incision. Bulson does not favor waiting for bulging of the membrane before incising. He has never seen any bad effects from an early incision done with proper antisepsis and precautions, but he has seen delayed cessation of discharge, impairment of hearing and even more serious results from waiting. Summing up his recommendations, he says: 1. The patient should be kept quiet, preferably in bed, and the more active the symptoms the more necessary the enforcement of this measure. 2. Secure a prompt and free movement of the bowels by calomel and salines. 3. Secure depletion of the vessels or the membrana tympani and of the tympanic cavity by leeches applied immediately in front of the tragus, and the osmotic effect of carbolic acid (10 per cent.) and glycerin tampons applied directly against the drum membrane. 4. Cleanse the pharyngeal and nasal mucous membrane with a saline antiseptic spray or douche. Remove any existing hypertrophied lymphoid tissue. 5. Advise cautious blowing of the nose to avoid infection of the tympanic cavity. 6. Apply dry heat for control of pain. 7. Incision of drum membrane under strict asepsis on appearance of pronounced redness of any portion of that organ when accompanied by pain, impairment of hearing, and other evidence of acute inflammation. 8. Following perforation of drum membrane, the use of aseptic dry gauze packing to exclude infection from without and also to withdraw the discharge from the tympanic cavity by capillary attraction. 9. Judicious inflation by Politzer's methods only after the acute symptoms have subsided or after the drum membrane has been opened to facilitate removal of discharges and to prevent adhesive changes in the sound-conducting apparatus.

Exophthalmic Goiter with Unusual Complications.—A. R. Elliott reports a case of exophthalmic goiter complicated with diabetes, Bright's disease, mitral disease, and retinitis. He discusses the association of glycosuria and this form of goiter, the influence of the latter and of Bright's disease in causing valvular lesions, and the differentiation of secondary cardiac lesions so caused from antecedent obscure endocarditis origin, as well as the question of the association of glycosuria and nephritis and the interpretation of retinitis in cases with both glycosuria and albuminuria. Glycosuria is not a very rare accompaniment of exophthalmic goiter, which generally antedates it. The most reasonable explanation, in Elliott's opinion, is that it is a toxic symptom, due to increased thyroid or parathroid activity, and as such it may have some prognostic importance. In his case the thyroidism clearly preceded the glycosuria by a considerable interval. In the case reported an analysis of the conditions existing indicated that the double mitral lesion found was due to an earlier endocarditis. While chronic Bright's disease is not reckoned among the epiphenomena of exophthalmic goiter, Elliott thinks it not impossible that the toxemia of the latter disease might set up degenerative renal changes if long enough continued. Diabetes and chronic Bright's disease are, on the contrary, very often associated, but in the case reported the latter is entirely out of proportion to the former, and displays an activity seldom seen in the nephritis of diabetes. Hence he thinks there is little likelihood of any relation between them. The interpretation of retinitis in cases with both glycosuria and albuminuria may be somewhat difficult, but it is a terminal symptom in both diseases, and if due to the diabetes the latter would not be amenable to medical control, as in the case reported. We have, therefore, co-existing in this patient exophthalmic goiter with secondary mild diabetes, valvular heart disease of antecedent endocarditic origin, a true renal albuminuria and albuminuric retinitis.

The Lancet, June 10, 1905.

Some Notes on Plague.—A. M. Elliott states his impressions derived from some 9,000 cases of the disease seen in India. He finds that local reaction after infection does not take place at the site of the latter, but in the nearest group of lymphatic glands. The seat of election is the lymphatic system. He does not believe that fowls, pigeons, or ducks contract the disease. Rats are the most susceptible animals, and next come guinea-pigs. Cats are susceptible to the disease, and may convey it to man. The channels of infection in any susceptible individual are (1) the skin and mucous membranes, (2) the alimentary canal, and (3) the respiratory system. Inguinal buboes occur more frequently in adult males than in women and children. Axillary buboes are more common in women than in men or children. Cervical buboes occur most frequently in children. From the channels of entrance of the infection we have three types of the disease, bubonic, pneumonic, and alimentary; either of these may take on a septicemic form, and death occurs from acute septicemia. The author is inclined to think that there are two forms of the plague bacillus—namely, the acute and the chronic. The latter continues the disease from one epidemic to the other, while the former gives the three types above mentioned, each type being entirely dependent on the channel of entrance, and the difference in death rates being to a great extent dependent on the group or groups of glands primarily infected. He thinks that in bubonic plague the gravity of the disease is greater when axillary and cervical glands are infected than when inguinal glands are attacked. As to treatment, he finds that cardiac stimulants are the only class of remedies offering any substantial aid. He mentions the fact that, as suppuration advances, the plague bacillus disappears, and suggests that the streptococci and staphylococci may be inimical to the bacillus. Antistreptococcus serum given in 21 cases led to 13 recoveries.

Some Remarks on Electrostatic Treatment.—J. C. Webb finds this form of electricity useful under the following conditions: (1) All acute or chronic inflammations not of microbe origin or due to pressure of a growth, congestion of the liver with constipation, chronic inflamed joints, inflammation of nerves or of their sheath—*e.g.* neuritis, neuralgias, lumbago, sciatica, ulcers, certain skin troubles, iflnammatory glandular swellings, etc., Certain laryngeal affections form another class that is greatly benefited by the wave current. (2) Certain cases of hemorrhoids in which the rectal veins are of a varicose character. (3) Certain cases of nervous disease—*e.g.* early cases of tabes, affections due to inflammation of the cord or meninges, neuralgias, headaches, spesmodic dysmenorrhea, and functional neuroses. The local and general effects of the current are described, and the author insists that each case shall be carefully studied, in order to enable the physician to make the proper application of the current. "Static treatment," without a definite application, is useless.

Dislocation of the Carpal Scaphoid.—A. Fullerton refers to the case of an elderly man who slipped on the pavement, striking heavily on the front of his wrist. Examination three weeks later showed a small, hard projection, irregular in shape, on the dorsum of the left wrist, the middle being about three-quarters of an inch from the radial border, and just below the level of the styloid process of the radius. The carpus was stiff and painful, and the bones appeared to be welded together. Flexion and extension were very limited. Several skiagrams were taken,

and revealed an undue sharpness of the styloid process of the radius and a want of distinctness and separation of the bones in the center of the carpus. It would appear from the skiagrams that the os magnum had become fused or closely joined to the neighboring carpal bones. A longitudinal incision was made on the dorsum over the projection. The scaphoid was found displaced backwards, and rotated so that the tubercle presented on the back of the carpus. The bone was removed, and two small fragments, flat and irregular in shape, about one-third of an inch in length and rather less in breadth, were found lying loose in the cavity left. It could not be determined whether these were originally chipped off from the radius or one of the carpal bones. Healing took place by first intention, but movements at the wrist joint and carpus are limited.

Successful Vaccination After the Onset of Smallpox.—F. Robinson refers to a series of 22 cases in which vaccination performed at dates varying from the first to the fifteenth day was successful in 8. In one instance success followed the vaccination on the third day of the eruption and the fifth day of the illness. In 7 of the whole series there was no history of any previous vaccination. Of the 8 successful cases, 4 were confluent in type, 2 were of the severe discrete type, while two were mild. The confluent cases were all severe, were all primarily unvaccinated, and one of the four resulted fatally. The author's impression from watching the cases was that a favorable therapeutic influence was exerted by the vaccinia.

British Medical Journal, June 10, 1905.

Spirochæte in Syphilis.—E. J. McWeeney refers to the work of Schaudinn and Hoffmann, in which they described organisms of spirochæte type which they find constantly present in syphilitic lesions. There are two sorts of organisms; one larger, thicker, and more readily stained, the other smaller, thinner, and staining with difficulty. The writer has also made investigations in this subject. In every one of the nine cases of undoubted syphilis in the primary and secondary stage which he has examined, spirochæte were easily demonstrated. In a case of advanced tertiary ulceration of the palate he failed to find the spirochæte, and he also missed it in a case of mucopurulent vaginitis, which was not considered to be syphilis by the medical attendant. These organisms that were found by the writer were spirally twisted, extremely delicate, actively motile, with peculiar corkscrew movement in either direction. The length averaged about 12μ. The thickness was too small to measure. As to staining reaction, the writer had the best results with the Giemsa mixture. The spirochæte were extracellular. In the fresh state, they were often attached to the pus cells by one end. A species of spirochæte has lately been shown by Schaudinn to be a stage in the life history of a trypanosome of the stone owl. This raises the query as to whether all spirochæte are also protozoa, and only stages in the life history of flagellates. Metchnikoff has found spirochæte in the syphilitic lesions which he has recently succeeded in producing in apes. It would not seem improbable that the microorganism may be etiologically connected with syphilis. It would be well to search for it in deep lesions beyond the reach of surface contamination.

Drug Treatment for Inebriety.—J. S. Bolton treated an inebriate as an out-patient. He began by injecting into the biceps muscle of the left arm a watery solution containing 1-60 gr. of strychnine hydrochloride and 1-30 gr. atropine sulphate. He also gave him a mixture every four hours containing red cinchona bark. The patient was fed at first on eggs, milk, soups, cocoa, and so on till appetite for solid food returned. The atropine affected the eyes till it interfered with his work. It also made his mouth dry. The writer then injected a large dose at night and a small dose in the morning. The patient was treated twice a day for forty days, then every other day for about four months. He is now well and strong, and has no desire for stimulants and is keeping straight. The writer believes that time and patience will secure the recovery of some of these cases.

A Factor in Seasickness.—A. Vavasour Elder emphasizes the importance of considering congestion of the liver as a factor in seasickness. When the voyage is begun with fine weather, travelers are apt to over-eat, sleep excessively, and neglect exercise. Sluggishness of the portal system results, and then trouble begins. The writer has found that the administration of calomel, gr. 1-8 to gr. 1-6 every hour till a grain has been taken, followed by a saline, will ameliorate seasickness. He refers to the danger of pushing cerebral depressants.

Münchener medizinische Wochenscrift, June 6, 1905.

The Preservation of Milk with Peroxide of Hydrogen.—Bauman reviews the various disadvantages attending the sterilization or partial sterilization of milk by means of heat or the addition of the ordinary chemical antiseptics, and describes a series of tests he has made with the object in view of determining the value of peroxide of hydrogen for this purpose. The results indicate that this measure should prove a commercially practical one, as although the addition of even .2 per cent. of the peroxide does not wholly sterilize raw milk, as little as .35 parts per thousand serve to exert a strongly bactericidal action on the ordinary pathogenic organisms occurring in milk, such as those of typhoid fever, cholera, dysentery, and tuberculosis. The activity of the antiseptic is greatly increased if the milk be heated to a temperature of 50°, and it was found that small quantities of it are completely eliminated from the milk in short periods of time through decomposition into water and oxygen, so that no foreign substance is left behind. Artificial digestion experiments seem to show that the digestibility of the milk does not suffer on the addition of peroxide of hydrogen, but the author says that this point can only be settled after clinical tests. There is therefore no indication that the addition of peroxide of hydrogen to milk exerts any undesirable effect, and if added promptly to milk collected as carefully as possible it should prove a satisfactory means of preservation.

Two Unusual Operations on the Gall Ducts.—Kehr describes these cases, in one of which he removed a stone from the common duct of a patient presenting complete transposition of the viscera, while in the other a secondary operation became necessary for the purpose of restoring permeability to a common duct that was the seat of a cicatricial stenosis following a previous cholecystectomy. The first patient was a man of 55, with somewhat atypical symptoms, but the diagnosis of transposition of the thoracic and abdominal viscera of impacted stone in the common duct made by both the attending physician and by Kehr was confirmed at the operation. The patient made a good recovery. The second patient was a woman, whose gall-bladder was removed on account of its inflammatory condition and the presence of stones. In ligating the unusually large cystic artery, or the cystic duct, the wall of the common duct must have been injured, for after the operation the discharge of bile through the wound could not be brought to a stop, and finally a secondary operation became necessary. The fistulous tract was dissected out, together with a short section of the common duct, which was completely occluded by cicatricial contraction. The two stumps were united by silk sutures, the ends of which were left long, so that they could be removed in due time, and the patient made a prompt recovery, with a perfectly healed abdominal wound.

Deutsche medizinsche Wochenschrift, June 1, 1901.

The Technique of Goiter Operations.—Reidel is very much in favor of performing these operations under local anesthesia, as he claims that not only is the mortality greatly reduced in this way, but also that the steps of the operation are much facilitated. For large growths, he makes a semicircular incision, beginning a short distance below each ear and curving downward and forward nearly to the jugulum. Large quantities of 1-1000 encaine solution are used to infiltrate the skin and the superficial muscles, which are cut across and dissected back with the skin flap. In the deeper layers, however, when the large vessels are to be ligated and the recurrent nerves identified, infiltration must be dispensed with, as it tends to distort the relations, and during these steps, as well as during the separation of the growth from the trachea the patient is likely to experience some discomfort. This is never extreme, however, and in spite of the fact that it is well known in the country round about Jena that at Riedel's clinic goiters are removed without a general anesthetic, the number of patients is steadily increasing. The author emphasizes the necessity for leaving a portion of the gland to prevent postoperative cachexia, and he also devotes some space to the discussion of malignant disease of the thyroid, which he considers beyond the reach of surgery.

Codeinism.—Pelz publishes what he considers the first case of true codeine habituation reported in the literature. The patient was a degenerate individual of 26, who had inherited constitutional depression, and after an attempt at suicide was given a prescription for codeine pills by a physician. The relief he experienced on taking the remedy impelled him to consume larger amounts, and a marked degree of habituation rapidly developed, until, as he alleged, he consumed 70 to 100 half-grain pills daily. Attempts to dispense with the drug resulted in restlessness, irritability, loss of energy, an intense longing for it, and finally even large doses did not produce the desired effect, and he resorted to other narcotics, though only to a slight extent. The treatment consisted in immediate withdrawal of the codeine, and only a very few doses of other sedatives were given. At first the abstinence symptoms were severe, and included insomnia, vomiting, and diarrhea, but in about two weeks most of the complaints had ceased, and after that

the patient made steady progress. The author believes that greater care should be taken in prescribing narcotics for those physically weak, as this man was, and he considers that it was this mental defect which made it possible for a codeine addiction to be developed. It is mainly because codeine is universally regarded as harmless that it is a source of danger, and it is essential to exercise precaution in putting it in the hands of patients.

Spirochæte Pallida in Syphilis, and Its Variations from Other Members of the Group.—Schaudinn and Hoffmann describe their observations on a microorganism occurring in the tissue juices of syphilitics. The organism which Schaudinn believes belongs to the protozoa, and is not to be confused with the genus spirillum, is a very delicate form, difficult to recognize by ordinary methods, and most easily demonstrated with Giemsa's eosin azure stain. It differs from other varieties in its small size, and in its corkscrew-like spiral form, the convolutions being numerous, regular, narrow, and deep, in distinction to the coarser and more refractile spirochæte refringens occurring in balonitis and papillomata. Metchnikoff has already succeeded in obtaining the spirochæte pallida from syphilitic lesions produced in monkeys, and the present authors found it in the splenic blood of a syphilitic the day before the appearance of the roseola. So far, the organism has been found in seven primary and nine secondary lesions, and in twelve typically enlarged inguinal glands. Buschke and Fischer also found it in the liver and spleen of a child that had died of congenital syphilis. Although Metchnikoff's results in monkeys are highly significant, the authors refrain from drawing any conclusions as to the etiological position of the organism, and content themselves with a statement of the facts.

French and Italian Journals.

An Old Hydatid Cyst of the Liver; Biliary Lithiasis.—Gaston Cotte describes this case. The patient was a woman, sixty-seven years old, with the following clinical history. She had entered the hospital with acute symptoms of calculous obstruction of the gall duct. A year before she had passed through a crisis of hepatic colic with jaundice, but for ten months she had had no further troubles of this nature. Palpation detected a distended gall-bladder the size of a fist, and very painful on pressure. The patient's general condition was bad, and she was very weak. Operation was out of the question, and medical treatment for lithiasis was instituted. The duct became permeable two days after her entrance to the hospital, and the gall-bladder diminished in size. Jaundice decreased and the temperature dropped. Nevertheless, the patient remained very weak. Six days after her entrance to the hospital, the parotid gland became inflamed, and pointed to the fact that an infection of the biliary passages existed. Twenty-four hours later the patient died. At autopsy, the gall-bladder was found to be filled with calculi; the hepatic duct was as large as a thumb, the liver, slightly hypertrophied, was peppered with small abscesses. On the convex surface of the organ there was a pocket filled with caseous matter, with calcified walls. Examination in the laboratory showed hydatid débris, and the characteristic hooklets of the echinococcus. The clinical history is interesting because in the evolution of a suppurative angiocholitis there was no thermic reaction or any febrile phenomenon. Examination of the liver showed that there had been spontaneous recovery of a hydatid cyst by cretaceous transformation of its wall. The coexistence of a hydatid cyst and lithiasis is interesting.—*Lyon Médical,* May, 1905.

Adenoepithelioma of the Thyroid Body Treated by Extirpation of the Tumor.—Latronche and Charrier had this patient under their charge. The tumor developed within a month. It was considered to be malignant. The patient was a young woman, twenty-six years old. Sabrazès gives the following histological report of the neoplasm. It was an adenoepithelioma of the thyroid gland, with a marked fibrous reaction. Certain segments of the tumor were almost entirely fibrous, while others had the structure of an almost normal gland, the elements of which were separated by dense connective tissue. Still other segments showed evidence of a neoplastic process passing beyond the limits of the adenoma. The writers state that the extirpation of this tumor was very difficult. There were strong adhesions to the laringotracheal tissues, and the growth pressed upon the lateral right wall of the trachea. At this point it sent out a prolongation, which had grown between the posterior surface of the trachea and the anterior surface of the esophagus, and which adhered closely to these two tubes. There were also adhesions to the large vessels in the neck. Nevertheless, it was taken out without much injury to these vessels; nor was the pneumogastric disturbed. The left lobe appeared normal, but it was never-

[illegible] extirpated.—*Journal de Médecine de Bordeaux,* May 21, 1905.

The Lactofarinaceous Régime in Intestinal Autointoxications.—M. Marcel Beauchant states that in the majority of cases intestinal autointoxication manifests itself by [illegible] symptoms, such as vomiting, colic, and diarrhœa. However, in other cases autointoxication shows itself only by symptoms relating to general nutrition, to the nervous system and to the skin. Intestinal antisepsis is considered absolutely insufficient to disinfect the intestine. All authorities agree on this point. The administration of large doses of antiseptics scarcely diminishes the number of microorganisms in the intestines. Repeated purgatives and enteroclysis diminish in large proportion the microbic flora, but they, nevertheless, only aid in this work, and their employment cannot be indefinitely continued. By introducing into the régime a large quantity of carbohydrates in which microbes do not find the necessary elements for their existence, and by cutting out as far as possible nitrogenous food from which the microorganisms of the intestines gain their nourishment, much may be done in these conditions. The lactofarinaceous diet, in cases of this kind, is a true antifermentative régime. Both milk and farinaceous foods have a true antiputrid action, but the advantage rests with the latter. Farinaceous foods are also admirably supported in all affections of the large intestine. These foods, then, should be associated with milk, for they correct, to a certain extent, the inconveniences of the former and make it more digestible. Combe has shown that when albumin is ingested, about five times its volume of farinaceous food should be taken. The lactofarinaceous régime constitutes to a certain extent the ideal régime for combating intestinal putrefaction. But in order to lessen the severity of the treatment in cases which are not serious, nitrogenous food may be given in the form of meat, but at the same time five times its weight of farinaceous food should always be ingested.—*Revue Française de Médecine et de Chirurgie,* May 22, 1905.

Phenic Acid in Traumatic Meningoencephalitis.—E. Fossataro injected pure phenic acid into the brain of the guinea pig, and later examined the hemispheres and cerebellum to ascertain if there was a destructive effect on the brain. He found that pure phenic acid did not affect the nerve cells or fibers, but was dispersed and absorbed in the vascular plexuses of the brain. There it exerted its coagulating effect, and produced general thrombosis and rupture of the walls of the capillaries, and innumerable small hemorrhagic foci. He believes that the resistance of animals differs under injections of phenic acid.—*Annali di Medicina Navale,* April, 1905.

Surgery of the Stomach.—Casati, after operating on a large number of cases of cancer of the stomach, concludes that it is useless and even harmful to operate on such cases when it is not possible to interfere at an early stage of the disease. He advises the physician to have recourse to the surgeon as soon as possible after the disease is diagnosed, and not to let the case go until the disease is in an advanced stage, when surgical interference is useless. The neighboring lymphatics should not be permitted to become infected, because it is not possible to extirpate all these glands, as can be done in cancer of the breast.—*La Riforma Medica,* May 27, 1905.

Modifications of the Leucocyte Formula from the Injection of Iodoiodurate in Children.—A. B. Gianasso gives us the result of the treatment of tuberculous cases in children by the injection of iodoiodurate solution. The cases were of orthopedic nature, and no other treatment was given except rest in bed when needed, or immobilization of the joints. He first injected a solution of peroxide of hydrogen, then the iodoiodurate of potassium, which holds the iodine in a nascent state, in 2 per cent. solution. This was followed by slight massage of the locality of the injection. The iodine has a general action as well as a local one. It is easily absorbed and passes rapidly into the circulation. It increases the power of resistance and of defense against the tubercle bacillus, promotes metabolism, increase elimination of old cells and the substitution of new and vital ones, and places the body in a condition to resist the development of the bacilli. The iodine is fixed by the tissue cells and the red blood globules. Twenty cases were treated, most of them affected with bony, or articular tuberculosis. One had cervical adenitis, one pulmonary tuberculosis. They were from 13 to 14 years of age. Blood examinations were made before and after treatment, and injections were given daily, about thirty being given. The author's conclusions are given as follows: These injections have a general, as well as a local action, exciting lymphoid activity. This produces a leucocytosis, with preponderance of [illegible] cells, representing a reaction of the organisms by the phagocytic action of the white blood cells against the tubercle bacilli.—*La Riforma Medica,* May 27, 1905.

Book Reviews.

Les Nerfs du Cœur, Anatomie et Physiologie. Avec un Préface sur les Rapports de la Médecine avec la Physiologie et la Bactériologie. Par Élie de Cyon. Avec 45 figures dans le texte. Paris: Félix Alcan, 1905.

We have here a monograph on the innervation of the heart from the pen of the veteran physiologist Cyon. Before entering on the subject-matter of the book, the author in a most readable and entertaining preface shows the importance of the study of physiology to the student of medicine; he points out the limitations of bacteriology, and pays his respects to Metchnikoff in a somewhat severe criticism of the phagocytic theory. In addition to his own work on the innervation of the heart, Cyon passes in review the observations and researches of other workers in the same field; in successive chapters there are discussed the intracardiac nerves, the extracardiac nerves, the depressor nerve (of Cyon), circumstances which modify the action of the cardiac nerves and the laws governing the same; and finally there is a chapter on the various theories that have been entertained concerning the nerves of the heart. The volume is instructive and important; and coming, as it does, from one whose name has been connected for nearly forty years with the physiology of the heart, it carries with it the imprint of authority.

De l'Endométrite et de la Métrite Parenchymateuse Infectieuses (Étude clinique et thérapeutique). Par le Dr. E. Ozenne, Ancien interne des hôpitaux, Ancien chef de clinique adjoint de la Faculté, Chirurgien de Saint-Lazare. Paris: A. Maloine, 1905.

This little book treats of inflammatory conditions of the uterus caused by infection. It is written from the clinical standpoint, and deals with the etiology, symptoms, course, treatment, and sequelæ of these conditions. Under the head of treatment, a dozen pages are devoted to hydrotherapy.

The Open-Air Treatment of Pulmonary Tuberculosis. By F. W. Burton-Fanning, M.D., Physician to the Kelling Open-Air Sanatorium, etc. New York: Cassell & Co., 1905.

So many manuals have recently appeared on the subject of the open-air method of handling consumptives that each must be largely a repetition of its predecessor. The present one is to be commended for the simplicity of its statements and the fact that the author shows that elaborate institutions are not necessary for the good results which aerotherapy can secure. Special emphasis is laid upon the importance of helping the consumptive workingman after his discharge from the institution. Expenditure in this direction is often productive of much greater good in the aggregate than when money is spent on costly sanatoria. The pages have a hopeful tone running through them, while the chapter on diet is excellent.

Les Dégénérescences des Fibro-myomes de L'Uterus par G. Piquand, Ancien Interne Lauréat des Hôpiteaux, Prosecteur Provisoire à la Faculté de Médicine. Paris: G. Steinheil, 1905.

This is an interesting monograph on the subject of the degenerations occurring in uterine fibromyomata. The author's observations are based on the study of forty-two tumors of this type, the degeneration in eleven cases being fibrous, in six calcareous, in seven edematous, in five sarcomatous, in four cystic, suppurative and necrotic in one each, gangrenous in three, and malignant in four. The conclusion drawn is that thirty per cent. of fibromata undergo degeneration, and that the older plan of expectant treatment is distinctly dangerous on this account. Such changes are especially apt to take place during the menopause and the period immediately before it, so that operation is always to be advised before this time if possible, in order to avoid the complications otherwise likely to be encountered later.

König's Lehrbuch der Chirurgie. Allgemeine Chirurgie, von Dr. Otto Hildebrand, Vol. IV, 2nd Edition. Berlin: Aug. Hirschwald, 1905.

After his retirement from active surgical practice, König took up the task of personally supervising the completion of the eighth edition of his celebrated textbook on special surgery. His experience, particularly in certain lines, has been a most extensive one, and although he is now well advanced in years, the book still bears the marks of the freshness of youth. The present volume is noteworthy because it includes the branches of surgery with which his name is most intimately associated, viz., tuberculosis of bones and joints, and the diagnosis and treatment of fractures. Although fully presenting the views of others we find that the author's own individuality entirely pervades the book, and it is a question whether a scholarly treatise of this nature is not superior to the more extensive, but also disjointed, encyclopedic manuals. The present edition has been brought up to date as demanded by the progress in the various branches of surgery and especially the increased knowledge of bone surgery brought about by the use of the Roentgen rays.

The fourth volume on "General Surgery" has been edited and revised by Hildebrand of the Charité in Berlin. The extent of this portion of the work may be surmised by the fact that almost one thousand pages are occupied in its presentation, and the thoroughness which characterizes the other volumes is fully carried out in this, the concluding one. The material is too extensive for a detailed review.

Malformation of the Genital Organs of Women. By Ch. Debierre, Professor of Anatomy in the Medical Faculty at Lille. With 85 illustrations. Translated by J. Henry C. Simes, M.D., Emeritus Professor of Genito-urinary and Venereal Diseases in the Philadelphia Polyclinic. Philadelphia: P. Blakiston's Son & Co., 1905.

The first chapter of this book contains a brief sketch of the anatomy of the female genital organs; in it we note: the length of the uterus given in *cubic centimeters* (three times on one page), the expressions labium majorum and minorum frequently occur, the uterine and vaginal arteries are both said to be given off from the hypogastric artery, the clitoris and labia minora are said to be "the fundamental organs of copulation." Chapter two contains seven pages of the development of the genital organs. The third (and last) chapter describes the malformations. The sections on hypospadias and epispadias are furnished with illustrations of these conditions as they exist in *the male*. The translation is at times obscure; and the book, throughout, is sketchy and superficial.

Acute Contagious Diseases. By William M. Welch, M.D., Consulting Physician to the Municipal Hospital for Contagious and Infectious Diseases; Diagnostician to the Bureau of Health, etc., Philadelphia, and Jay F. Schamberg, A.B., M.D., Professor of Dermatology and of Infectious Eruptive Diseases, Philadelphia Polyclinic; Consulting Physician to the Municipal Hospital for Contagious and Infectious Diseases, and Assistant Diagnostician to the Philadelphia Bureau of Health, etc. Illustrated with 109 engravings and 61 full-page plates. Philadelphia and New York: Lea Brothers & Co., 1905.

The diseases discussed in the present volume are of such paramount importance to all medical men that the appearance of a new book devoted to their study is to be greeted with pleasure. The interest inspired by the work only increases on closer perusal, for it is in all respects thoroughly original and modern. The authors have had unusual opportunities for observation in the Municipal Hospital of Philadelphia and have used them to the utmost in producing this useful compilation of their experiences. As is natural, smallpox with its congeners is given the lion's share of space and its discussion occupies about one-third of the volume. The historical sketch of this disease and of Jenner's work is not the least satisfactory feature of the book, which throughout all its pages bears evidence of careful scholarship not in medical fields alone. Vaccinia, the relationship of cowpox to smallpox, variolous diseases of lower animals, smallpox and its sequelæ and complications, are the main headings under which the subject is elaborated. The illustrations, which are especially numerous in this section, for the most part are full page photographic plates depicting various stages and types of the exanthem, etc., and in view of the limited experience with the disease that most physicians fortunately have, they afford a very satisfactory substitute for clinical observation. The other diseases written on are chicken-pox, scarlatina, measles, rubella, typhus fever, and diphtheria. The closing chapter is on disinfection and is very good as far as it goes, but we feel that a space of four pages is hardly enough to allot to so important a topic. The eruption of typhus is shown on only a single plate, which is an excellent one, but considering the fact that the disease is so rarely seen in this country that the profession at large are compelled to draw their knowledge of it from books, it would seem that a larger number of illustrations might profitably be devoted to this subject. These are slight faults, however, and the practical character of the book should secure for it a wide circle of readers.

The Medical Epitome Series. Diseases of the Eye and Ear. A Manual for Students and Physicians. By Arthur N. Alling, M.D., Clinical Professor of Ophthalmology in Yale University, Department of Medicine, New Haven, Connecticut, and Ovidus Arthur Griffin, B.S., M.D., Late Demonstrator of Ophthalmology and Otology, University of Michigan, and Oculist and Aurist, University Hospital, Ann Harbor, Michigan. Philadelphia and New York: Lea Brothers & Co., 1905.

This volume is an epitome of diseases of the eye and ear; twenty chapters are devoted to the former, and five to the latter. The section on the eye would be improved by the addition of an introductory chapter on the anatomy of the eye. The book will be useful to students.

Society Reports.

AMERICAN GYNECOLOGICAL SOCIETY

Thirtieth Annual Meeting, Held at Niagara Falls, May 25, 26, and 27, 1905.

Dr. Emilius C. Dudley of Chicago, President.

An address of welcome was delivered by Dr. Carl G. Leo-Wolf, of Niagara Falls, which was appropriately responded to by Dr. Ely Van de Warker, of Syracuse.

Accidental Rupture of the Non-Parturient Uterus, with Report of Cases.—Dr. George W. Jarman of New York had seen five cases of accidental rupture of the non-parturient uterus. These were detailed. To draw some deductions from his own cases and those reported by others, it seemed to the author (1) that the operation of invading the cavity of the uterus should not be regarded lightly, and that the same care in the details of asepsis should be carried out as in a laparotomy. (2) That great care should be used in the introduction of steel dilators, at no time forcing them into the cavity of the uterus. (3) That as one's experience in gynecology increased, the use of the uterine sound decreased, and the fingers more and more frequently took the place of the curette to remove secundines from the uterus. (4) That sterile water was the best fluid for irrigating the uterine cavity. (5) That if a rupture or perforation of the uterine wall occurred, it was better to perform a laparotomy and assure one's self of the safety of the patient than to hope that no untoward results would ensue. (6) That if one could not be certain of the asepsis of the curettage, it was better to use a small drain through the vagina, with a slightly elevated posture of the patient, than to regret its non-use after the development of septic peritonitis. (7) That in properly conducted cases observed soon after the accident, there should be almost no mortality.

Dr. A. Palmer Dudley of New York had perforated the uterus four times. In one case, after introducing the instrument into the uterus, he withdrew what he supposed was a fungous growth of secundines, but which proved to be eight inches of the small intestine. The intestine was passed back through the opening made in the uterus, and the patient let alone. She had since borne two children.

Dr. Herman J. Boldt of New York said it was not always that a perforation of the uterus caused serious trouble. Great discrimination should be used in those cases in which there was danger. In all instances of criminal abortion where there was any suspicion that infection had taken place, the abdomen should invariably be opened. He had perforated the uterus a number of times, and had seen it perforated by others. In those instances of perforation of the uterus, the physician should do nothing except perhaps, insert a small piece of gauze through the cervix, and he believed the majority of cases would recover.

Dr. Eugene Boise of Grand Rapids, Michigan, reported two cases of perforation of the uterus, one of which occurred in 1871. The physician in attendance passed a sound clear up to the handle. Nothing was done, and the patient developed no symptoms. In the other case the uterus was perforated with a curette; the cavity was thoroughly washed out, the patient put to bed, without anything further being done, and she made an uninterrupted recovery.

Dr. Fernand Henrotin of Chicago had seen five cases in which the uterus was perforated. One was accidental. One was the result of the work of an abortionist, and on opening the abdomen, the patient being septic nine days after the supposed operation, the speaker found a bougie nine inches long in the abdominal cavity. The patient recovered after undergoing a severe trial.

Dr. Andrew F. Currier of New York agreed with the previous speakers that in many of the cases in which perforation of the uterus had occurred, no damage would result if the intestine had not been withdrawn. If there was a mere puncture of the uterus, if the woman was not septic, it was safe to leave her alone and do just as little manipulation as possible. But supposing the uterus was in a soft, friable condition, one was presented with the alternative of either closing the perforation or of removing the uterus. In many cases the removal of the uterus was preferable, and more than likely would result in more benefit to the patient than the mere closure of the hole. The key to successful treatment was complete drainage, and if there was already a condition of sepsis in the uterus, and one simply closed the wound, he was by no means sure that the sepsis would not continue. Therefore, in cases of that kind it would be prudent to remove the uterus, leaving the wound in the vagina open, and establishing free drainage.

Dr. A. Lapthorn Smith of Montreal did not think it was the curette which was responsible in most cases for perforation of the uterus. He confessed to having perforated the uterus about six or eight times. He had no fear of the result if the parts were thoroughly aseptic.

Dr. Clement Cleveland of New York had perforated the uterus with a sharp curette on one occasion when he was talking to his class about the carefulness with which the instrument should be used. The patient was to be operated upon for a lacerated cervix and lacerated perineum. He postponed this operation, put the patient to bed, and no bad results followed. The Society should exercise its influence toward eliminating the sharp curette from the bag of the general practitioner, or else it should be relegated to the junk heap. It was fraught with the greatest harm to future women if it was used in the careless way it was to-day.

Dr. William E. Moseley of Baltimore said both the dull and sharp curettes had their place. Personally, he first introduced the dull instrument for diagnostic purposes, and then the question as to whether the dull or sharp curette should be used depended upon the character of the tissues one had to deal with. There were some cases in which there was more danger of perforation of the uterus from the use of the dull than from that of the sharp curette.

Dr. William H. Wathen of Louisville did not think the dull curette had any place in the surgery of an experienced gynecologist. The man who could not use a sharp curette without injuring his patient had better refer his cases to someone who could. Occasionally, he admitted, cases were reported where the uterus had been perforated by experienced operators. Curettage should be done by the sharp curette, or decidual remains should be removed by the finger, if possible.

Dr. Ely Van de Warker of Syracuse, N. Y., stated that uterine curettage was attended with more or less danger, and should be confined to the hands of good gynecologists, and rarely ever, or never, done by the general practitioner.

Dr. Seth C. Gordon of Portland, Maine, said occasionally he had pushed a sound through the uterus, but on leaving the patient alone he had not seen any harm result.

Dr. Philander A. Harris of Paterson, N. J., had perforated the uterus twice, once through the corpus posteriorly, and once anteriorly. The perforation posteriorly was done by the curette, and the one anteriorly by his dilator. With his present dilator there was a device attached to it which registered the exact number of pounds exerted by the operator in dilating the cervix.

Dr. T. A. Reamy of Cincinnati, Ohio, had perforated the uterus with a sharp curette within the past two years. He curetted a woman a short time ago, whose condition was such that his consultant was in doubt as to whether there was cancer of the body or the result of a chronic endometritis. The speaker in curetting the uterus rather thoroughly, perforated it. A pelvic abscess resulted from the perforation, which was opened, and the patient made a good recovery.

Dr. Emilius C. Dudley of Chicago stated that within five weeks he perforated a uterus with a curette. The uterine wall was not more than the thirty-second of an inch thick, due to a localized pathological condition. A considerable quantity of bloody fluid was found in the cul-de-sac of Douglas, which was sponged out, the abdominal cavity flushed out with salt solution, and after closing the wound

in the uterus with a purse-string suture, the abdominal wound was closed, and the patient made a good recovery.

The Treatment of Retroversion of the Uterus by Shortening the Uterosacral Ligaments.—Dr. ARTHUR W. JOHNSTONE of Cincinnati stated that the first step in either retroversion or prolapse was due to a stretching of the uterosacral ligaments. This was proven by clinical experiences and a study of the comparative anatomy of the subject. This stretching was most commonly due to a low grade of infection spreading to these ligaments from the uterus or other contiguous structures, that made them lose their tone. A few cases were due to direct violence. The operation consisted in shortening the uterosacral ligaments through the vaginal incision. The uterus was replaced and prolapse cured. Shock was *nil*, and convalescence smooth.

A New Plan of Procedure in Retrouterine Displacements.—Dr. E. E. MONTGOMERY of Philadelphia stated that retrodisplacements of the uterus more frequently demanded restoration to normal position than any other form of displacement. Nature's forces should be imitated as far as possible in relieving malpositions. The Alexander operation and its modifications were in this line of procedure. Its usefulness was limited to the uncomplicated and mobile uteri, in which operative interference was least demanded. The majority of the intraabdominal operations on the round ligament employed the best part of the ligament in their manipulation and left unaffected its weakest portion. The various operations of ventrofixation and ventrosuspension were departures from the normal, placed the uterus in abnormal relation, and rendered painful and difficult the performance of its normal functions. The vaginal procedures required considerable dissection, were ineffective in restoring normal relations, and were to that degree to be condemned. The operative procedure he would suggest was a combination of operative procedures employed by Gilliam, Ferguson, and Simpson. It permitted of treatment of diseased ovaries and tubes, left the uterus a freely movable organ, supported it by normal elastic and muscular structure capable of undergoing evolution and involution, and, finally, afforded no opportunity for the formation of unfortunate adhesions.

Arteriosclerosis of the Uterus as a Factor in Uterine Hemorrhage.—Dr. PALMER FINDLEY of Chicago read a paper on this subject, in which he gave a résumé of all cases, and reported four new ones. The writer dealt exclusively with the so-called essential or idiopathic hemorrhages, the cause of which was not definitely determined. He argued that arteriosclerosis of the uterus was not the prime factor in bringing about these obscure hemorrhages. In his opinion, muscular insufficiency was the underlying cause, and the sclerosed vessels were but contributing factors. He drew the following conclusions: "1. Metritis, as a primary lesion and independent of infection, is not accorded the consideration which the frequency of its occurrence and its clinical significance would warrant. 2. The muscular fibers of the uterine wall have an important function in controlling the caliber of the blood vessels, and hence in regulating the blood supply to the uterus, as evinced in the relaxed condition of the uterine wall during menstruation, in postabortion, and postpartum hemorrhages, and in the free bleeding which accompanies curettage when the uterus has relaxed under the irritable influence of the curette. In all these conditions the hemorrhages are controlled by the contractions of the uterus. 3. Any event which lowers the muscular tone of the uterus may occasion an abnormal loss of blood into the endometrium and uterine cavity. 4. Prominent among the factors which contribute to muscular atony in the uterus are the wasting diseases, anemias, and acute febrile diseases, which are not infrequently accompanied and followed by uterine hemorrhages as the result of weakened support to the vesical walls. 5. Fibrosis uteri is a far more common cause of muscular insufficiency. The building up of connective tissue in the uterine wall at the expense of the muscular elements is the result of long-continued passive congestion, which in turn is due to numerous general and local lesions, such as an incompetent heart, obstructions in the lungs, liver, kidney, and spleen, abdominal swellings, varicose veins of the pelvis, and uterine displacements. 6. The walls of the blood-vessels share in these hyperplastic changes, in that the media and adventitious coats of the vessels are thickened. In this manner the elasticity of the vessel walls is impaired, and if the lumen of the vessels is not narrowed by contraction of the vessel walls, and thickening of the intima, there will be added reasons for various engorgements of the uterine wall and capillary oozing at the endometrium. In such cases the prime factor in the causation of uterine hemorrhages is the muscular incompetency; the thickened vessel walls and the remote embarrassments to the circulation are but contributory factors. 7. This condition of the vessel walls is to be distinguished from the arteriobliterans of the normal senile uterus, in which the vessels are partially or wholly obliterated by the thickened intima. In such cases hemorrhages do not occur, for the reason that the blood supply is greatly diminished. 8. In none of the recorded cases were hemorrhages seen to come from ruptured blood-vessels, nor were aneurysms of the arteries seen in the uterine wall. On the contrary, the escaped blood was farthest removed from the sclerosed vessels and more evidently capillary. We are therefore not justified in ascribing the hemorrhages directly to the sclerosed vessels. 9. The diagnosis can only be made by first excluding all other possible causes, such as polyps, carcinoma, and fibroids. 10. Hysterectomy has been frequently resorted to after repeated curettages have failed. Palliative methods—rest, ergot, styptic applications to the bleeding surface, and finally tamponading the uterine cavity—may be resorted to, but have repeatedly failed."

Postoperative Vomiting.—Dr. EUGENE BOISE of Grand Rapids, Michigan, said it was assumed as proved that there was a vomiting center from which all impulses toward vomiting were sent. These impulses might be received through various channels. The conditions that led to postoperative vomiting were numerous. They might be grouped as (1) those conditions pertaining to the anesthetic; (2) those pertaining to the general condition and surroundings of the patient; and (3) those pertaining to the stomach. The anesthetic caused vomiting (1) by its direct irritant action on the vomiting center; (2) by causing a toxemia, and (3) by saturating the secretions of the stomach. The conditions pertaining to the stomach were (1) chronic, such as atony, dilation, chronic disease of the mucous membrane, etc. (2) Acute, as saturation of the tissues and secretions of the stomach by the anesthetic. Treatment must therefore be preventive as well as curative, involving greater care in the preparation of the patient. Four things must be kept in mind: (1) The abnormal irritability of the vomiting center; (2) the condition of the stomach; (3) the condition of the blood; and (4) the condition of elimination. Treatment must be adapted to the conditions found. Theoretically, the indications were to obtund the sensitiveness of the vomiting center; to neutralize, if possible, the irritant character of the anesthetic; to cleanse and soothe the stomach; to keep the patient quiet in order to avoid circulatory disturbances; to aid elimination, and to support the patient and nourish the irritated nerve centers by rectal feeding when indicated.

Dr. A. LAPTHORN SMITH emphasized the necessity and importance of preliminary preparation of patients. Careful attention should be given to diet, to getting the bowels thoroughly cleaned out, so as to reduce the amount of vomiting after operation to a minimum. He advocated the drinking of large quantities of hot water by patients to wash out the ether that had been swallowed during its administration. Hot water taken in this way amounted to the same thing as gastric lavage.

Dr. MATTHEW D. MANN did not believe the character of

the anesthetic had as much to do with vomiting as the amount of the anesthetic. The more deeply a patient was anesthetized, the greater the amount of anesthetic used, and the longer time it took the patient to get rid of it, the more the vomiting center was irritated. For three years he had been using ether, preceding it by chloride of ethyl. He had done an operation, lasting forty-five minutes, with two or three ounces of ether, when preceded by chloride of ethyl. Since following this method, vomiting had been greatly reduced, and in many instances the patients had not vomited at all.

Dr. A. Palmer Dudley said that if operators considered the preparatory measures mentioned by Dr. Mann, there would be less reflex action on the part of the stomach in postoperative work.

Dr. Andrew F. Currier thought the preliminary administration of chloride of ethyl or nitrous oxide, as had been his custom recently, was much more satisfactory than the prolonged and irritating effects which came from the first stage of anesthesia through the administration of ether alone. One could lay down as a principle that given a very careful administration of the anesthetic and a small quantity, one would have much less trouble afterwards from vomiting.

Dr. C. C. Frederick agreed with Dr. Mann as to the preliminary use of chloride of ethyl, followed by ether or chloroform. For a year and a half or more he had begun anesthesia with chloride of ethyl, getting the patient under its influence rapidly, then changing to ether or chloroform. Vomiting was much less by this combination.

Dr. Arthur W. Johnstone attributed the great decrease in the amount of vomiting after operations largely to careful preliminary preparation of his patients.

Dr. Daniel H. Craig of Boston did not consider eserine in any sense a specific against postoperative vomiting, but he thought it had the same effect on cases of postoperative vomiting as gastric lavage, whether resorted to before the patient left the table, or later. The effect of small doses of calomel given before operation, or divided doses of it after operation, was the stimulation of normal peristaltic action. With lavage the stomach was emptied. Eserine had no effect on the motility of the stomach itself, but it did in reestablishing or preventing stoppage of intestinal peristalsis. Eserine did the work far more efficiently and effectively than divided doses of calomel, which necessitated giving the patient medicine by the mouth at a time when she was nauseated and unprepared to take it.

Dr. Malcolm McLean of New York said one should give as little of the anesthetic as possible. Anesthetics should be given by men who were skilled in this work. By giving a preliminary anesthetic, such as chloride of ethyl or nitrous oxide, the preparation was such that when ether or chloroform was given, large toxic doses of it were not carried through the circulation so as to poison the patient in the postoperative stage.

Dr. George Gellhorn of St. Louis stated that for about a year he had employed as a preliminary the hypodermic injection of scopolamin-morphine, about an hour before operation. This combination arrested secretions from the mucous membrane of the mouth and throat. He gave scopolamin and morphine in the proportions of 1-150 of a grain of scopolamin to 1-6 of a grain of morphine. The effect was that the mouth and throat were absolutely dry, and remained so during the operation, and the amount of ether used was materially minimized.

Dr. Reuben Peterson said his experience had been different from that of Dr. Gellhorn in the use of morphine and atropine. He had used this combination for years, giving about 1-6 of a grain of morphine, and 1-150 of a grain of atropine, about three-quarters of an hour before the anesthetic was given. Before he used these drugs there used to be excessive secretion; there was gurgling, so that the mouth and throat had to be swabbed out; but since their use this had almost entirely ceased. He had not attributed the absence of vomiting to the use of these drugs entirely, but to thorough preliminary preparation of the patient, and to better methods of administering chloroform and ether.

Dr. Edward P. Davis said that the remarks made concerned patients with whom there had been abundant time for preparation. One was obliged sometimes to operate upon emergency cases, as ruptured ectopic gestation. In these postoperative vomiting might be very depressing and dangerous. What could be done to prevent it? While the patient was on the table, and before the operation was quite completed, intravenous saline transfusion or injection would prevent postoperative vomiting as well as prevent shock.

Dr. Fernand Henrotin said that one of the most important factors in the reduction of vomiting, as well as in the reduction of shock and of making a patient's recovery reasonably smooth, was washing out the stomach. For a little over a year he had been resorting to quick anesthesia with nitrous oxide preparatory to the administration of ether, using as little of the anesthetic as possible, immediately washing out the stomach thoroughly after every operation, and giving a hypodermic injection of eserine before the patient was taken off the table. The use of this combination had made an immense difference in the results of his general operative work.

Dr. J. Wesley Bovee thought the proper procedure was to prepare patients as well as the conditions would permit, and do it with proper discrimination. Then came the proper administration of the anesthetic, giving as little as possible of it, and steadily, not irregularly. After the administration of the anesthetic he had found the administration of oxygen for fifteen to twenty minutes to be the most satisfactory of anything he had used. He objected to the use of morphine because there were so many cases of renal complication in which the use of this drug would handicap the operator.

(*To be Continued.*)

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held April 24, 1905.

Dr. Henry S. Stearns in the Chair.

The evening was devoted to a consideration, solely from the standpoint of the general practitioner, of certain infections and inflammations, including the following three papers:

Diagnosis and Treatment of Acute Diseases of the Accessory Sinuses of the Nose from the Standpoint of the General Practitioner.—Dr. C. G. Coakley read this paper. He said that the profession at large seemed to have only a vague idea of the diseases of the accessory sinuses of the nose. The milder cases got well with little or no treatment and the more severe types became chronic and finally reached the specialist for relief for their "catarrh." He felt that many of the patients that were seen to-day could have been saved much of their suffering had their diseases been diagnosed early and properly treated at that time. The paper was presented with the object of directing attention to the acute stages of inflammation of these sinuses and the means employed in diagnosing and treating them. He then called attention to the structure and position of these various sinuses. As the mucous membrane lining all these cavities was directly continuous at some point with the mucous membrane lining the nose, it necessarily followed that every attack of acute inflammation of the nasal mucous membrane was accompanied by a greater or less involvement of the mucous membrane lining the accessory sinuses.

The antrum might become acutely inflamed either as a result of extension from a diseased process in the nasal cavity or from a suppurative otitis or periostitis of the tooth-sockets. There was a yellowish, thick mucopulent discharge from the nose which was quite profuse. Fre-

quently pain was complained of in the upper teeth, and perhaps inability to chew food, usually the bicuspids and first and second molars being the most sensitive. If secondary to diseased teeth there might be bulging over the superior maxilla. The lower eyelid was occasionally edematous. Pressure over the external surface of the antrum seldom elicited pain. At times the only pain complained of had been intense supraorbital neuralgia, probably a reflex pain from pressure on the infraorbital nerve as it passed along the roof of the antrum. Not infrequently pain was complained of in the temporal region of the affected side. Intracranial complications followed disease of the antrum less frequently than when any of the other accessory sinuses of the nose was involved, on account of its anatomical position.

The subjective symptoms in the frontal sinus were a profuse discharge from the corresponding nasal cavity and intense supraorbital pain, usually throbbing in character. Tapping the forehead internal to the supraorbital notch always aggravated the pain. Pressure on the under surface of the frontal bone near the nose produced great pain, whereas corresponding pressure on the opposite side was painless. The frontal pain was greatly increased by blowing the nose, and this was almost pathognomonic of frontal sinusitis. Headache might be referred to the temporal region, the vertex, or the occipital region. In severe cases with insufficient drainage there were some redness and edema of the upper eyelid. Such symptoms indicated considerable tension on the walls of the cavity from retained secretion and demanded prompt relief on account of the danger of cerebral complications.

Ethmoiditis, he said, occurred so infrequently that it was difficult to give symptoms due to it. The painful regions were varied, depending upon whether the anterior or posterior group of cells were involved. In the former case the pain was most acute along the side of the nose near the inner angle of the orbit. Supraorbital pain was not infrequent, although pain on tapping the frontal bone and on pressing the orbital surface of the frontal bone was seldom very great. In the posterior group of cells the pain was quite commonly referred to deep in the head, back of the eye or in the eye itself. Occipital pain might be very intense.

In diseases of the sphenoid the discharge was nearly always post-nasal, a dropping in the throat as the patients expressed it. The pain was very much like that of involvement of the posterior ethmoidal cells. When several of these groups of sinuses were involved the pain was so general that at one time patients would refer it to one portion of the head and then to another. Their frequent expression was that the head felt as full as though it were ready to burst. Dizziness or vertigo or unsteadiness of gait was occasionally observed.

The treatment of acute sinus disease he classed under two heads, constitutional and local. Opium and morphine were contraindicated because they masked the progress of the disease. Hot fomentations oftentimes gave great relief and he saw no objection to their use. Some preferred the ice-bag. He advised that the patient be allowed to try first heat and then cold and use that which afforded the greater relief. The local treatment in a case of acute sinus disease consisted in the establishment of an efficient drainage. The swollen mucous membrane of the nose must be contracted and kept so. In cases of moderate severity this was all that was necessary, for the frontal, ethmoid and sphenoidal cells would empty themselves if given a chance. As for the antrum, proper ventilation of the nose allowed the compressed air resulting from blowing the nose to force out of the antrum the bulk of the secretion. Adrenalin (1—10,000) sprayed into the nose once in two or three hours kept the nasal mucous membrane well contracted. Occasionally it became necessary to use as an adjuvant a one or two per cent. solution of cocaine. This was the only condition in which one was warranted in prescribing a cocaine spray for a patient. The thick, tenacious secretion should be removed by syringing the nose, care being taken to do it properly and not induce an otitis media. The least irritating material for irrigation should be used and saline solution with the same proportion of bicarbonate of sodium as of salt, he said, would be found to be the best. Following this treatment, if the symptoms were not relieved, the cause should be sought for and remedied, or else artificial openings made for the purpose of drainage. The most frequent obstructions to drainage were a thickened or cystic middle turbinate and polypi which could not be contracted sufficiently. Then one must have recourse to resection of the anterior third of this body, and the removal of the polypi by snare and forceps. It was not necessary to remove the entire middle turbinate. The opening of the antrum was badly located for the purpose of drainage and consequently one frequently had to puncture and wash out the cavity with saline solution. It was seldom necessary to do this oftener than every other day.

Non-Suppurative Conditions of the Ear Leading to Deafness.—Dr. A. B. Duel read this paper. Leaving out of consideration malformations, malignant, and benign tumors, concussions, chemical and thermal influences, and many other causes, he said the points in the history to be elicited from a patient with deafness (not accompanied by suppuration) practically were as follows: Was the impairment of hearing of long (chronic) or short (acute) duration? Was the onset sudden or gradual? Was it unilateral or bilateral? If bilateral, did it begin in both ears simultaneously? Was the impairment worse in one ear than the other? Was the ear in which the trouble originated still the worse one? Was there tinnitus? If so, of what character (high or low pitch, constant, intermittent, or pulsating)? Was there any vertigo? Was there any pain? Was there any obstruction to nasal respiration? Was there a gouty, rheumatic, or syphilitic diathesis? Next a physical examination of the ears should be made to determine if there was any mechanical obstruction in the meatus and to determine the condition of the drum membrane. The nose, nasopharynx, and pharynx should be inspected for any possible cause of obstruction to respiration or interference with the ventilation of the middle ear by the eustachian tubes. The tuning forks should then be used to note whether the impairment resulted from a lesion in the conducting apparatus (middle-ear deafness) or in the receiving apparatus (internal-ear nerve deafness). The distances at which forced whisper, the tick of a watch or acoumeter was heard should be then noted. With the data thus obtained it would be possible to make a diagnosis in most instances. Broadly speaking, he said there were two classes of cases which would present themselves, the first in which the deafness could not be improved by any local treatment, the defect being beyond its influence, and a second class which might be entirely cured or greatly benefited by local treatment, since the defect in hearing was largely mechanical, owing to interference with the conducting apparatus. In the first class of cases would come all purely labyrinthine or central cases which would be characterized by referring a tuning fork on the forehead to the better ear; air conduction would be better than bone conduction, and the latter would be diminished as compared with a normal ear; low tones would be heard better than higher tones, and the associated tinnitus was likely to be high pitched and continuous rather than low pitched and intermittent or pulsating. In the second class of cases, on the other hand, there was impairment of hearing because of interference with the entrance of sound waves either by mechanical obstruction of the external meatus or by imperfect ventilation of the middle ear, or by structural changes in the conducting mechanism which impeded the freedom of their movements. All such cases were characterized on functional testing by referring the note of a tuning fork placed on the forehead to the poorer ear, by hearing better by bone than by air conduction, and by hearing by bone conduction better in the deaf than in the normal ear. High tones were heard better than low, and

with certain exceptions hearing was temporarily greatly benefited by inflation of the tympanum. The accompanying tinnitus was likely to be low pitched, and might be intermitting or pulsating. This class included acute and chronic eustachian tubal catarrh and acute and chronic hypertrophic catarrhal otitis media. It was his belief that these conditions were all due to the same process, viz., owing to obstruction in the nose, nasopharynx, or pharynx, a congestion took place in the enstachian tubes and this extended to the middle ear as an acute, active congestion, or, by mechanical obstruction, caused a passive congestion. Should this process continue unrelieved, the congestion caused an hypertrophy of the submucous tissue first in the tube and later in the tympanum. These chronic inflammations were subject to acute exerbations, and hence the remissions and exacerbations of catarrhal deafness. This deafness due, in the early stages, entirely to interference with ventilation of the middle ear by obstruction of the tube, gradually added mechanical disturbance due to the hypertrophic changes in the tympanum. In the later stages of some cases, atrophy of this hypertrophied tissue took place, but too late to be of any benefit to the hearing, since the distortion of the tympanum had already placed it beyond repair. This, then, he said, was the class of cases for which something could be done, and it should be done quickly. A child with occasional attacks of earache, and the subject of mouth breathing, with slight deafness, was the subject for chronic catarrhal deafness in later years. The obstruction to the proper ventilation of the tympanum should be removed at once. A patient of any age having deafness from a lesion of the conducting apparatus, which showed temporary improvement on inflation, should have the advantage of a thorough removal of any obstruction which might be causing congestion of the middle ear and also the widening of the calibre of the eustachian tube if the patency was not sufficient to ventilate the middle ear properly. This should be followed by inflations of the middle ear, as long as improvement took place. He said it was surprising to see the number of cases in which injury had been done to the canal or the tympanic membrane by efforts to remove impacted cerumen or other foreign bodies by the use of curettes and other instruments. Impacted cerumen should be removed only by the use of a large syringe capable of expelling water with considerable force. With a slight alkaline solution directed against the canal at the junction of the plug of cerumen, the canal meanwhile being straightened by pulling backward or backward and upward on the auricle, would almost invariably force out the plug *en masse*. It was practically never necessary to send a patient away for a few days with ear drops to soften the plug. Other foreign bodies, such as peas, beans, beads, etc., should always be removed when possible by forcible syringing of the canal.

The Etiology, Diagnosis, and Treatment of Mastoiditis.—Dr. Wendell C. Phillips read this paper. Acute suppurative otitis media, he said, was the result of the introduction of infection into the tympanic cavity through the eustachian tube; therefore, any infective process in the nose and nasopharynx whereby an unusual amount of infective material accumulated in the spaces, furnished sufficient ammunition to supply the infection for middle ear suppuration. Even the mildest efforts at relief by blowing could force the infection through the eustachian tube. As types of these infections he mentioned scarlet fever, measles, diphtheria, typhoid fever, and grip and other infectious colds. As remote causes he mentioned adenoids and hypertrophied tonsils. With regard to chronic suppuration of the middle ear, this existed simply and solely as the result of incompetent and neglected treatment of the acute stage and, barring tuberculosis, syphilis, and malignancy, there should be no such thing. He was of the opinion that in nearly every case of acute middle ear suppuration the involvement reached not only the attic, but also the mastoid antrum, and he explained this by means of a rough sketch which showed the anatomical relations. While the usual route by which the infection reached the mastoid cells was the aditus ad antrum, it could not be denied that occasionally there seemed to be a primary infection of the cells, and this was usually attributed to the circulatory and lymphatic systems. Careless treatment or neglect of middle ear suppuration played an important part as a cause of mastoiditis, and he said the physician's responsibility was not fully assumed if he neglected to fulfill the following requirements: (1) That the patient with acute middle ear suppuration should be confined to his bed; (2) that no oily or other substances which might become rancid should be allowed in the external canal; (3) that the external auditory canal be properly sterilized; (4) that a free paracentesis be performed as soon as pus had accumulated in the tympanic cavity; (5) that subsequent to this all cleanly measures should be adopted; (6) that a visual examination of the canal be frequently made.

The diagnosis of acute suppuration of the middle ear was based upon two prominent symptoms, pain and the appearance of the drum membrane. The proper diagnosis of mastoiditis must be based upon the following symptoms: There was dull, deep seated pain in the mastoid region, chiefly located over the antrum, or radiating in various directions from the mastoid process. Tenderness on pressure upon the mastoid process was a constant symptom, and this first appeared usually in the region of the antrum, and was elicited only upon deep pressure at times. Another important symptom was the drooping or bulging of the posterior superior canal wall together with the attic membrane. There was no characteristic temperature in mastoiditis. A symptom not often described was the peculiar anxious expression of the countenance with a more or less fixed position of the head and neck, which was almost always present when the disease had becomed established. The mastoid invasion might be accompanied by a sudden cessation of the pus flow, or again it might rapidly increase; the latter indicated a wider area of infection with a free exit.

The patient should be placed in bed at the very commencement, and special effort should be made to sterilize the external auditory canal by free douching with a 1 to 5,000 bichloride solution at a temperature from 100 to 110 degrees; this procedure should be repeated at intervals of one hour after the discharge had become established. So soon as pus accumulated in the tympanic cavity the drum membrane should be incised. If local bloodletting seemed necessary, the incision should be carried outward into the auditory canal, making sure to go through the periosteum. This was a far more surgical procedure than the use of leeches. The subsequent treatment consisted in maintaining free drainage and observing the laws of cleanliness. A cure was usually effected in from two to three days to as many weeks. Only complicated cases ran a longer course.

Chronic suppurative otitis media was rarely unaccompanied by necrosis which had gone beyond the confines of the tympanum and the nearness of the tympanic cavity to the brain, and the lateral sinus should make this a matter of very serious consideration. The amount of necrosis should be determined and all unhealthy granulation tissue should be removed. The so-called dry treatment proved the most efficacious. At the daily visits various remedies, of which formaldehyde solution, peroxide of hydrogen, chromic acid and bichloride solutions were types, should be employed, after which a light packing of plain sterile or iodoform gauze might be introduced. When the treatments were less frequent the patient should douche the ear several times daily with a warm bichloride solution. This form of treatment might require weeks or even months to effect a cure. Two methods of operating were made use of, the intratympanic (removal of the ossicles and curettage through the external auditory canal), and the radical operation known as the Stacke, or Schwartze-Stacke. The

intratympanic operation was permissible when a fairly confident diagnosis had been made that the necrosis was confined to the ossicles and tympanic ring. The radial operation was the more scientific, but required skill and a minute knowledge of the anatomy of the temporal bone, and was performed for the purpose of removing all portions of necrosed bone together with sufficient healthy bone to leave one large cavity which included the mastoid antrum, additus, and tympanum.

After dwelling briefly upon the preventive and operative treatment of mastoiditis, Dr. Phillips offered the following conclusions: (1) Patients suffering from acute otitis media should be confined to the bed during the acute inflammatory stage. (2) Recurrent suppurative otitis media was usually the result of adenoid vegetations in the vault of the pharynx, plus infection. (3) Chronic suppurative otitis media existed only as a result of incompetent or neglected treatment of the acute stage. (4) Grippe infection produced a large proportion of the serious complications of middle ear suppuration. (5) A chronic suppurative and necrotic process in the middle ear, considering its environment, called for serious consideration. (6) The practitioners of medicine should acquire sufficient skill to make an intelligent examination of the drum membrane and sufficient familiarity with symptoms to diagnosticate the serious complications. (7) Well developed suppuration which had gone beyond the confines of the mastoid antrum and involved the mastoid cells in general called for external operative interference. (8) in the treatment of chronic suppurative otitis media local measures should be exhausted before considering radical operative interference. (9) Failure to cure chronic suppurative cases, especially when evidences of necrosis were present, should be followed by some form of operation. The Stacke or Schwartze-Stacke operations, while rather serious in nature and required marked skill, offered the best hope of permanent cure. (10) In the consideration of both the mastoid operation and the radical operation for chronic suppurative otitis media wise conservatism should guide the action of the surgeon.

Drs. Coffin and Berens discussed these papers.

The Ethics of Advertising.—Apropos of a resolution passed at the December meeting of the Society: "That in any directory or list other than a medical one, it is undesirable that any data should appear other than the name, address, and telephone number, and that the use of more prominent type for one name than another is to be severely deprecated," the following resolution was offered and hotly discussed: "Resolved: That the insertion of any advertisement exclusive of name, address, office hours, or telephone number in any directory other than a medical one should be sufficient cause for expulsion of such member from the Society and the disbarment of candidates for membership." During a heated discussion, a motion to adjourn was made and unanimously carried.

ILLINOIS STATE MEDICAL SOCIETY.

Fifty-fifth Annual Meeting, Held at Rock Island, May 16, 17, and 18, 1905.

Dr. William E. Quine of Chicago, President.

(*Continued from page 959.*)

Surgical Section.

Surgery of the Stomach.—Dr. Arthur Dean Bevan of Chicago, said that stomach surgery to-day stood out as the most gratifying surgical field in the process of rapid development. This fact was perfectly patent that the demonstrated value of surgical procedures in treating stomach lesions warranted a much wider application of such methods than were at present practiced. His plea was that the cases must be carefully selected, and the surgeon must be sure that an operation was strongly indicated. Cases that could be cured by a summer's outing or by carefully selected diet should not be operated upon; nor should hopeless cases be operated. He discussed the surgery of the stomach under two heads: (1) Surgical treatment of carcinoma of the stomach, and (2) the surgical treatment of ulcer and its complications and sequelæ. If cases of carcinoma of the stomach were early diagnosed and operated upon at a time when the entire focus of disease could be removed, a cure could be effected. As to stomach ulcer, when intelligent medical treatment failed and the symptoms returned and persisted, then and not until then did the uncomplicated stomach ulcer become a surgical problem. The great majority of cases of perforation of the stomach by ulcer could be saved by early surgical interference. The surgery of the stomach was advancing. The profession should keep pace with it and give the patient the benefits of its demonstrated possibilities.

Dr. Carl E. Black of Jacksonville discussed the surgery of the bile tracts, and Dr. Emerson M. Sutton of Peoria discussed the possibilities of surgery of the duodenum.

Dr. M. L. Harris of Chicago spoke of the surgical treatment of injuries to the spleen due to subcutaneous penetrating wounds; the value of splenectomy in certain anemias associated with enlargements of the spleen.

Surgical Tuberculosis.—Dr. William E. Guthrie of Bloomington in discussing this subject, said that while physicians should study how to help tuberculous patients by the proper removal of diseased tissues, they should not forget that vastly more necessary was the conservation of the power of resistance of the patient to disease through suitable hygiene and forced feeding. He who would treat tuberculosis in any form successfully must have for his watchword ever, Feed, feed, feed.

Tuberculous Nephritis.—Dr. Robert Christie of Quincy reviewed the literature with reference to comparative frequency, and alluded to the more recent investigations and observations, discussing the modes of infection, primary, secondary, metastatic atypical cases, without characteristic symptoms, other than localized tumefaction. He reported a case in which he did a primary abdominal nephrectomy, followed by recovery of the patient.

Errors in the Diagnosis of Abdominal Troubles.—Dr. Clifford U. Collins of Peoria said that protection in diagnosis marked the highest development in science and medicine. With a correct diagnosis it was not hard to institute the proper treatment. The development of diagnosis had been a difficult process marked by many errors. While one was endeavoring to approach perfection in diagnosis, it was highly probable that errors would always be made. Although errors were annoying, each one conveyed a lesson, and if studied and interpreted correctly, would result in much good to the examiner. The keeping of complete case records would permit of close and careful study of each error and lead to success, because "Success does not consist in not making any mistakes, but in not making the same mistake twice."

Congenital Club-Foot.—Drs. John Ridlon and Charles E. Eikenbary of Chicago contributed a joint paper, in which they briefly discussed the varieties of congenital club-foot; also the anatomy of congenital equinovarus and the theories of its causation. The paper chiefly discussed the subject of treatment by manipulation, by braces, by the Thomas wrench, by hand modeling, with the patient anesthetized, by the Granton osteoclast, by simple tenotomies supplemented by modeling, or the use of the wrench, or the osteoclast by the Phelps open incision and Jonas' modification of it, and by linear and cuneiform osteotomies, and enucleation of the astragalus. The methods of after-treatment by plaster splints and by braces were briefly considered and the statistics of Dr. Ridlon's cases for the past twelve years were given.

Stricture of Esophagus Following Typhoid Fever.—Dr. S. C. Plummer of Chicago reported a case of stricture of the esophagus following typhoid fever. The case was one of typhoid fever with severe relapse, symptoms of stricture

immediately following. The patient was treated by sound. There was gradual tightening until swallowing even of water was impossible. Under anesthesia an unsuccessful attempt was made to pass the stricture. A gastrostomy was performed; there was relaxation of the stricture after four months of absolute closure. Diliatation of the stricture was resorted to, and an operation made for closure of the gastric fistula.

Colloid Carcinoma of the Cecum.—Dr. PLUMMER reported this case, in which an operation was performed for appendicitis three years previously. Excision of the cecum and ascending colon was done, with lateral anastomosis by Murphy button of the ileum to the transverse colon. There was recovery from the operation, with restoration of health, followed by recurrence.

Penetrating Wound of Liver.—In this case Dr. PLUMMER said the injury was produced by a small missile, a portion of a dynamite cap. Laparotomy was done, but the foreign body not found. It was evidently embedded in the liver. The liver wound was closed, and the patient recovered without complications.

Gastroenteroptosis.—This patient had symptoms simulating appendicitis. The transverse colon was found in the shape of the letter V. The gastrohepatic omentum was abnormally long. The gastrohepatic omentum and transverse mesocolon were each folded upon itself and stitched, followed by permanent relief of the symptoms.

Dr. FERNAND HENROTIN of Chicago made some remarks concerning when and how to treat septic pelvic affections of women by vaginal incision and drainage.

Diagnosis and Pathology of Neoplasms of the Brain.—Dr. HUGH T. PATRICK of Chicago in discussing the pathology, said that the most frequent tumors were glioma, sarcoma, and solitary tubercles. He enumerated the less frequent forms. Stricture, the manner of growth, and the physical properties of more frequent tumors were pointed out. As to diagnosis, the determination of intracranial neoplasms was generally easy. Exact localization was generally difficult, frequently impossible. He mentioned the classical symptoms of brain tumor and the points of differential diagnosis. Tumor might simulate apoplexy. General paresis, arteriosclerosis, nephritis, migraine, etc., were discussed in connection with brain tumors; also the symptoms indicating the seat of growth.

Insanity Following Skull Injuries.—Dr. E. MAMMEN of Bloomington spoke of contusions, concussions, location of injuries, fractures, and symptoms following skull injuries. The symptoms were sometimes slow in development. He spoke of the changes in tissue at the site of injury, also operation, relief from pressure, relief by the removal of changed tissues and of cirrhotic bone. He cited cases and gave the results.

Cerebral Infection from Middle-Ear Disease.—Dr. NORVAL H. PIERCE of Chicago referred to the anatomical paths by which suppurations within the temporal bone reached the contents of the calvarium. He discussed the character of the primary inflammations which produced intracranial complications, as well as the influence of locality of the primary inflammation on the different intracranial complications. Purulent inflammations of the dura and the extradural abscess were discussed. He referred to meningitis and meningoencephalitis serosa following suppurations within the temporal bone; also to phlebitis and thrombosis of the dural sinuses and the jugular vein. Reference was made to isolated thrombosis of the jugular bulb, also to otitic brain abscess.

Prophylaxis of Syphilis.—Dr. ALFRED SCHALEK of Chicago said there was renewed activity in this direction among the medical profession in recent times. The reasons were not an increase in the number of cases, nor a more severe course of the disease, but better statistis, and the present improved prophylactic measures against other infective diseases. The spread of syphilis could be limited by means which applied to the general public and to the individual. The former included control of prostitution, but had proven a failure. Impracticable also was the suggested compulsory report of cases by physicians. A better measure was the education of the public as to the nature of the disease. Instructions should be given how to avoid infection innocently. He made a plea for increased facilities for treatment in hospitals and dispensaries. The author thought that at the present time the most valuable prophylaxis against syphilis ought to be practised by the medical profession in their relations with their patients. Since no methods were known to abort the disease after infection occurred, the most important duty was a thorough treatment.

Some Cases Demanding Removal of the Eye of Interest to the Physician and Surgeon.—Dr. J. BROWN LORING of Chicago discussed the responsibility resting on the physician and surgeon, as well as the ophthalmologist, with regard to the treatment of blind eyes. Reports were given of three cases of sarcoma, one of glioma, and five of iridocyclitis of various origin, causing or threatening sympathetic ophthalmia. The first four cases indicated danger to life, the others danger to sight. Statistics were given as to the frequency of sympathetic ophthalmia. Attention was called to the unsatisfactory and at times contradictory manner in which the subject of treating eyes blind from iridocyclitis was discussed in modern textbooks. A plea was made for a more radical treatment of these cases from every standpoint.

The Commerce of Surgery.—Dr. FERNAND HENROTIN of Chicago, in selecting this subject for his address, said he did not wish to apologize for the prevailing forms of commercialism which tended to degrade the medical profession. He spoke for the future, and bespoke an unbiased, calm decision upon the best methods of eradicating or minimizing existing evils. A considerable part of these might rightly be attributed to the course of life of the very men who condemned them so strenuously. In the keen competition of the battle of life they had forgotten that for ethical function equity should be supplemented by kindness; omission and a lack of perception, not commission. Within the bounds of law they had lost sight of negative beneficence. They often began by being commercial until beyond want, and now they were moralists. They held more positions than they could fill satisfactorily; they performed more operations than they could do full justice to, or overlooked the care of. They often opposed the rise of their peers and particularly their superiors on their faculties; they boasted of their large fees and their annual income, exciting the cupidity of their fellows, all of which was properly within the law, but was an element in the development of present conditions. Add to that the elements which he had shown and one would have the reason for commercialism. All of this writing was a plea for the exercise of negative beneficence on the part of the profession in regard to this whole question. While proven violations of the law of ethical conduct should be given publicity and be visited by just penalty, wholesale denunciations should be decently omitted as tending to disorganize the ranks and doing injury to men whose mistakes had resulted from force of circumstances and surroundings and the strenuousness of the age they lived in. Let those who were successful make it their duty to help others to a firm footing beyond the need of dubious methods. To eradicate impure commercialism entirely might be impossible, as it was founded on man's inheritance of original sin and because reasonable commercialism was an incentive in life, but it was not impossible by harmonious cooperation to cultivate a desire for a higher standard by combining justice and beneficence. The practice of self-restraint and renunciation was not happiness, though it might be something bett

Dr. GEORGE E. SHAMBAUGH of Chicago discussed the indications for opening the mastoid process in cases of acute empyema of the cells when there was an absence of signs over the external surface of the mastoid.

Dr. George Schmauch of Chicago discussed the diagnosis and treatment of rupture of the uterus.

Dr. L. H. Nickerson of Quincy followed with a paper in which he discussed the diagnosis and treatment of laceration of the vaginal portion of the uterus and fornix vaginae.

Immediate Diagnosis and Treatment of Lacerations of the Vagina and Pelvic Floor and Perineum.—Dr. C. S. Bacon of Chicago classified these tears as external and internal. In both there were many grades, and either might be simple or combined with those of the other class. Diagnosis concerned both the finding of these lacerations and determining their extent and importance. Both touch and inspection were employed. The pain caused could be disregarded, but the risk of infection was considerable and should be carefully considered. Hirst's proposed delay of all examination and operation till the end of a week was not practicable, and the author favored immediate examination and repair, but only with as careful asepsis as would be employed in a secondary operation. In a non-operative labor, when there was no hemorrhage with the expulsion of the head, and no severe external tear, there would be no internal laceration, and an internal examination was unnecessary. Hemorrhage was rarely an indication for operation in vaginal and perineal tears. The bad results of unrepaired lacerations were generally the reasons for operation. Spontaneous repair was a delusion. Proper preparation was very important in all repair operations. Especial attention should be given to vaginal lacerations that involved the pelvic diaphragm and extended into the central attachments of the accessory diaphragm, but did not implicate the skin surface. Here the skin bridge might be cut and the repair made as in a combined vaginal and perineal laceration, or the internal suture could be applied so as to bring in opposition the divided structures. The perineal sutures of silkworm gut must not be tied too tightly. In a complete rupture the method of restoring the rectal tube by passing the suture through the rectal mucous membrane was preferred to the passing of the suture from the perineal side. The author preferred cutting the ends of the perineal sutures short, and discarded powders. Catheterization was unnecessary. A wide occlusive dressing, fastened by the four corners to the abdominal bandage, was much better than the ordinary dressing held by the T bandage. Chief stress was laid on attention to details in preparation for and technic of operation, without which poor results and total failures furnished grounds for discarding immediate operations.

Pelvic Infections in Women.—Dr. T. J. Watkins of Chicago said that pelvic infection was preferable to pelvic inflammation as a name to designate the disease, as infection injured and destroyed tissues, whereas inflammation tended to conserve tissue. The author limited his paper to a discussion of some of the practical points of pelvic infections. He spoke of the importance of the disease, and said that the same principles were involved in pelvic infections as in infections in other parts of the body. He considered the etiology, pathology, symptomatology, diagnosis, prognosis, and treatment.. The importance of prophylaxis was pointed out. Topical applications were often of little or no value. Conservatism during the acute stage was of great importance. Spontaneous and complete recoveries sometimes ensued.

Dr. E. Wyllys Andrews of Chicago discussed perigastric adhesions after gallstone operations, pointed out their surgical importance, and described a new operation for their relief.

Intussusception in Infancy and Childhood.—Dr. J. H. Hess of Chicago read a paper with this title, in which he had collected 1,028 cases with statistics. (1) Intussusception demanded an early diagnosis and immediate treatment. (2) Abstinence from all food; and, far more important, purgation must absolutely be prohibited. The question of sedatives in the form of opium, etc., must rest with the physician. (3) Irrigation might be tried once or twice under the propor conditions and in properly selected cases. Preparation for immediate laparotomy should be made in case of failure; complete anesthesia. Hot salt solution or plain water might be used under a pressure of not more than three feet, the fluid being allowed to remain in the bowel not less than ten minutes. He pointed out the contraindications to irrigation, as follows: "(1) Recurrence after a previous complete or partial reduction. (2) The very acute and severe types of this disease which result in early destruction of the bowel wall, but which cases are fortunately not the most frequent type. (3) Where there are signs of beginning gangrene or ulceration evidenced by subnormal temperature, profound toxemia, and other septic symptoms. (4) Enteric intussusceptions. (5) Laparotomy should follow failure of irrigation without delay." One should attempt simple reduction from below upward. In irreducible cases, resection within the bowel in selected cases, or when this is not feasible, resection with end-to-end anastomosis should be attempted if the patient's condition makes it practicable. An artificial anus or simple packing about the bowel requires a secondary and only too frequently a fatal operation.

Bronchoscopy for the Removal of Foreign Bodies from the Lung.—Dr. E. Fletcher Ingals of Chicago mentioned previously reported cases of the removal of foreign bodies by the upper and lower routes. He described the instruments used in removing these bodies, with illumination by electric lamps, as in urethroscopy. There was danger when the tube was introduced into the bronchus of the affected side, owing to the fact that it might shut off the air from the other lung. He spoke of the use of a small opening in the tube to keep the tube free from pus and mucus. He reported recent cases, and exhibited an emergency device for removing foreign bodies.

Dr. James W. Twitchell of Belleville reported a case in which recovery occurred following a perforated wound of the intestine without surgical interference.

The following papers were also read and discussed:

"The Value and Place of Duodeno-Choledochotomy in Gallstone Surgery," by Dr. John C. Hancock of Dubuque, Ia.; "Inversion of the Uterus, with Report of Cases," by Dr. P. L. Markley of Rockford; "Pathology and Diagnosis of the Lesions of the Spinal Cord and Peripheral Nerves," by Dr. Frank P. Norbury of Jacksonville; "Malignancy in Uterine Myomata," by Dr. Henry F. Lewis of Chicago.

Officers.—The following officers were elected for the ensuing year: *President,* Dr. H. C. Mitchell, Carbondale; *First Vice-President,* Dr. W. K. Newcomb, Champaign; *Second Vice-President,* Dr. M. S. Marcy, Peoria; *Secretary,* Dr. E. W. Weis, Ottawa, re-elected; *Treasurer,* Dr. E. J. Brown, Decatur, re-elected. Springfield was selected as the place for holding the next annual meeting.

Philadelphia County Medical Society.

At a stated meeting held May 10, Dr. S. C. Burns presented for Dr. W. L. Rodman "A Case of Gastrostomy" occurring in a man about 50 years old, with obstruction at the cardiac extremity of the stomach, with ability to swallow only small amounts of fluid. The patient was greatly emaciated and debilitated, and a fistulous opening was made into the stomach through an incision close to and parallel with the left costal margin after the viscus had been attached to the parietal peritoneum and included within the margins of the divided rectus muscle. In this way a sphincteric action was obtained, preventing the leakage of gastric juices and excoriation of the cutaneous surface surrounding the fistula. The patient gained in weight and strength after the operation. Dr. H. Emerson Wetherill presented a centrifugal apparatus operated on the principal of the whirligig. The device was simple and portable and the cubes were graduated so that the amount of precipitate could be read from a scale etched on the glass. Dr. M. H. Fussell read a paper entitled "Two Cases of Malignant Endocarditis." One occurred in a lad with a history of previous typhoid fever anl later presenting symptoms suggestive of appendicitis. There was severe pain in the right illac fossa, with distinct leucocytosis and a somewhat hectic tempera-

ture. In addition, murmurs were audible at the aortic orifice, and on this account operative intervention was refrained from. Death resulted and examination disclosed the presence of ulcerative endocarditis involving the aortic valves. In the second case also there was a history of typhoid fever, but typhoid bacilli were not agglutinated and rendered immobile by the blood-serum. On account of the size of the heart and especially the enlargement of the right side of the viscus, the presence of leucocytosis, of enlargement of the spleen and of a presystolic murmur at the mitral orifice a diagnosis of malignant endocarditis was made. After death the mitral valve was found the seat of large vegetations and the spleen contained several infarcts. Dr. Fussell dwelt especially on the resemblance of the first case to one of appendicitis and the history of typhoid fever in both cases, the apparent symptoms of the latter being merely due to the endocarditis. Dr. NORMAN B. GWYN read a paper entitled "Typhoid Fever; Accidental Infection with the Bacillus of Malignant Edema or the Gas-bacillus, with the Symptoms of Intrathoracic Irritation." Hypodermoclysis was employed in the course of treatment and was followed by the development of subcutaneous emphysema in the vicinity of the needle puncture in one situation. Large bacilli suggestive of hay-bacilli were isolated from the fluid present. Dr. G. BETTON MASSEY read a paper entitled "Some Aspects of the Cancer Problem," in which he dwelt upon the primarily local origin of the disease and the need of early recognition and prompt removal by the cautery, by cataphoresis, or by the knife. Patients thus treated must subsequently be kept under frequent observation for a long period of time, in order to guard against recurrence.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending June 17, 1905:

	Cases	Deaths
Measles	740	31
Diphtheria and Croup	281	31
Scarlet Fever	142	5
Smallpox	.....	.....
Chickenpox	108	.....
Tuberculosis	373	162
Typhoid Fever	45	13
Cerebrospinal Meningitis	68	42
Typhus Fever	.....	.....
Yellow Fever	.....	.....
Cholera	.....	.....
Totals	1,765	284

Dangers of Illuminating Gas.—The perils of the domestic use of modern fuel and illuminating gas, now so generally used, are pointed out by Dr. H. Leffmann. The coal gas formerly employed was comparatively non-toxic, and its characteristic odor was a danger warning, but the modern water gas that has so largely replaced it in common use, with its larger content of carbon monoxid and its comparative lack of odor, is far more dangerous. Accidents from this cause are far more frequent than formerly, and carbolic acid and illuminating gas have replaced for suicides and accidental poisonings, the arsenic and laudanum of the Civil War period. A sleeper can easily absorb a fatal amount of modern water gas without being aroused, and Leffmann shows by a simple calculation how a very small percentage of carbon monoxid—less than ½ a grain, for example, to 100 c.c. of blood—can render useless the hemoglobin of the latter. Gas stoves for cooking are used generally only in warm weather when natural ventilation is good, and the danger from them is therefore lessened, but their burners are seldom furnished with a collar to regulate the air supply, and the combustion is therefore liable to be irregular, and deleterious gases are given out. Gas "stoves" or heaters connected with the gas pipes by rubber tubing are objectionable on account of the liability of leakage, which is very great unless the very best tubing material is used. The stopcock on the heater is especially objectionable, as it is the one most convenient to use, and when used the leakage through the tube can go on unchecked. The precautions recommended by Leffmann are: Prevention of sale of inferior tubing; having no stopcocks on heaters unless they are connected with house mains by metal pipes with tight joints and such construction as will prevent the rubber tube, even when of the best quality, remaining in free connection with the house main when the gas is not lighted. He would also have heaters constructed so as to give a larger radiator effect with a given gas consumption, and would have them placed only where the products of combustion can escape freely into the chimney. All burners on the Bunsen principle should be provided with collars to regulate the air supply, and purchasers should be instructed in their use. The commonly u[illegible] illuminating mantles may also be objectionable by interfering with combustion, especially when worn or displaced, and the flexible tube of the ordinary drop-light be also a source of danger like that of the heater.—*Journal of the American Medical Association.*

Folliculitis Necrotica is designated by Pernet ("Syphilitic and non-Syphilitic Affections," London, 1904) as acne necrotisans et exulcerans serpiginosa nasi and described as a rare condition which requires to be differentiated from syphilis. It occurs acutely about the end of the nose as small papules, which become purulent or necrotic, leading to numerous scars with fresh papules forming at the borders.

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ending June 17, 1905:

SMALLPOX—UNITED STATES

			CASES	DEATH
District of Columbia, Washington	June	3–10	1	
Florida, Jacksonville	June	1–15	1	
Illinois, Danville	June	1–15	1	
Indiana, South Bend	June	3–10	1	
Louisiana, New Orleans	June	3–10	10	
Massachusetts, Lowell	June	3–10	1

INDEX.

A.

Abdomen, gunshot wounds of the, 895; methods of exploring the, 32; penetrating wounds of the, 229; significance of certain symptoms in the, 33, 957.

Abdominal and pelvic organs, ptosis of the, 74; incisions for exploration of the appendix and ulcer of the stomach, 548; operations, results of, 867; pain, diagnosis and treatment of, 787; pain, umbilical hernia as a source of, 795; pregnancy, a difficult diagnosis in a case of, 856; region, diagnosis of diseases of the upper, 185; section, after-treatment of, 116, 238; section, after-treatment of with eserine salicylate, 467; section, exploratory, 386; tumors, 795; viscera, treatment of acute perforations of the, 72; viscera, parotitis following disease of the, 29.

Abscess, acute periurethral, 617.

Academy of Medicine, Dr. Jacobi's gift to the, 179; in London, 463; New York, see *New York Academy of Medicine;* of Toledo and Lucas County, 180.

Accommodation, subnormal, and premature presbyopia, 147.

Acetanilid poisoning, 838, 960.

Aceton celloidin imbedding, 631.

Acid intoxication, 390.

Acidification of the liver and spleen a sign of death, 870.

Ackerman, William, microscopical examination of the fasting stomach contents, and its diagnostic value, 527.

Acne and its treatment, 408, 433; treatment of, by means of a new procedure, 909.

Acnitis and folliclis, 660.

Acromegaly, a case of, 114, 838.

Actinobacillosis versus actinomycosis, 19.

Actinomycosis, 950.

Adams-Stokes syndrome, 852.

Addison's disease, a case of apparent, with cure, 913; recovery in a case of, 949.

Adenocarcinoma of the uterus, 633.

Adenoid vegetations, removal of, curing exophthalmos and chorea, 270; in the adult, 746.

Adolescence in girls, 754.

Adrenal extract, action of on the kidney, 750.

Adrenalin chloride, hypodermic use of, in asthma, 431; synthesis of, 782.

Adulteration, a law to check, 621.

Advertising, ethics of, 994.

Aërophagia and flatulence, 649.

Agglutination tests, fallacies in the, 669.

Air tract, hyperplasia of the mucous membrane of the upper, 387.

Albuminous bodies from the same organisms, separated by the precipitation test, 869.

Albuminuria, acute circumscribed edema with orthostatic, 829; orthostatic, 429.

Albuminosuria, myelopathic, 269.

Alcohol, action of, on the circulation, 938; and smoking, evil effects of, on soldiers, 140; as food, 668; dressings, value of, 470; inhalations of strong, 599; in health and disease, 356; in marksmanship, 14; in the tropics, 24; legislative aspects of, 357; question, a contribution to the, 392; relation of to insanity, 860; substitutes for, 356.

Alcoholic borderline psychoses, 468; insanity, 879.

Alcoholism, tremor as a sign of, 948.

Aldermanic solicitude for children, 782.

Alexander-Adam's operation, 498, 749.

Alimentary canal, recent advances in the knowledge of the movements and innervation of the, 952.

Alimentation, subcutaneous, 268.

Allen, Charles W., the treatment of eczema and impetigo in children, 768.

Allport, Frank, examination of the sight and hearing of school children in Vermont, 225.

Alopecia areata, treatment of, with currents of high frequency, 352.

Alpha Kappa Kappa, 102.

Alpha Society banquet, 863.

Alpine disasters, 92.

Alternating currents, effects of on dogs, 551.

Amberg, Emil, some points of view in regard to the time when to perform myringotomy and the mastoid operation, 573.

Ambidexterity, 149.

Amblyopia ex anopsia, 281.

Amebas, infecting the human intestine, observations on, 947.

Amebiasis, 588.

Amebic dysentery, a fatal case of, 311.

American Anti-Tuberculosis League, 702; Association for the Advancement of Science, 20; Association of Genitourinary Surgeons, 977; Association of Pathologists and Bacteriologists, 662; Gastroenterological Association, 702; Laryngological Association, 942; Laryngological, Rhinological and Otological Society, 941; Medical Association, incorporation of the, 423; Medical Association; was it reorganized as it should be, and will it accomplish what it otherwise might? 903, 943; Medical Colleges, Association of, 621; Medical Society for the Study of Inebriety and Alcohol, 941; medicine, 67; Neurological Association, 941; Public Health Association, 61, 101; Therapeutic Society, 78.

American Journal of Surgery, 623.

Anal fissure, 66.

Anemia, a case of pernicious, 917; a case of pernicious, improved by treatment, 186; attempt to produce an antibody in, 25; bloodstains in pernicious, 271; nervous symptoms accompanying pernicious, 107; splenic, 34.

Anemic patients, effects of anesthesia and operations on, 398.

Anesthesia in rectal diseases, local versus general, 150; local, by cataphoresis and by mechanical pressure, 467; sterile water, 707.

Anesthetic, choice of, and method of administration of a general, 213, 675.

Anesthetization by the high pressure method, 28.

Aneurysm, extirpation of popliteal, 109; the Matas operation for, 230.

Angina pectoris, alterations in the heart following, 378.

Angioneurotic edema, 546; edema of solar origin, 628.

Ankle, a rare dislocation of the, 630.

Ankylostorniasis, significance of eosinophibia in, 349; the tongue in, 338.

Anthrax, successfully treated by Sclavo's serum, 348.

Antibodies, a new method of obtaining, 70.

Antistreptococcus serum, clinical use of, 427.

Antituberculosis League, American, 263.

Antrum of Highmore, transillumination of the, 549.

Anuria due to renal calculus, recovery, 710.

Aortic, atheroma, experimental, 790; regurgitation with chronic miliary tuberculosis in a man of twenty-two, 375.

Aortitis, acute, 908.

Apoplexy, prevention of, 840.

Appendicitis, 506, 629; a method of extension of the gridiron operation for, 508; and pregnancy, 27; as a manifestation of erythema multiforme, 385; collection of foreign bodies in, 749; etiology and pathology of, 879, 976; in a child, 218; in women, 74; leucocytosis in, 69, 70; medical aspects of acute, 298; new etiology and prophylaxis of, 379; pathology of, 947; peculiarities of, in women, 469; perilous calms of, 307; prospects and vicissitudes of, after operation, 469; relation of mechanical distention to the etiology of, 552; treatment of fulminating, 786; work, my changes of view in, 810.

Appendicostomy, in the treatment of colitis, 715.

Appendix and gall bladder, anatomical peculiarities of, 827; decapsulation of the, 575; ideal method of removing the, 26; invaginating probe for the, 118; medical treatment of the inflamed, 907; operations, experiences in 1000, 789; palpation of the, and appendicitis larvata, 387; tuberculosis of the, 910.

Aramian, M., the use of extract of dichondra as a bactericide in diphtheria, 335.

Arizona Medical Association, 979.

Armies in the field, prevention of disease in, 740.

Army ambulances, 421.

Army Medical Corps, examinations, 302; increase in the, 62; needs of the, 179.

Arterial hypertension, chronic, 185.

Arteries, a new method of closing wounds of the, 20.

Arteriosclerosis, affecting the nervous system, 194; an address on, 186; experimental, 837.

Arthritis, analysis of forty cases, with especial reference to diagnosis, 918; deformans, large doses of arsenic in, 347; organic acid in the urine in rheumatoid, 30; serum treatment in multiple infections, 667.
Arthrotomy, 74.
Arthur, William H., preliminary report on the treatment of chronic dysentery, by irrigation of the colon, through the vermiform appendix or an opening into the cecum, 455.
Artificial respiration, 910; dangers of Schultz's method of, 349; wider use of, 708.
Ascites, clinical significance of, 878; in a woman 22 years old, 632; treatment of, in cirrhosis, 510.
Asepsis and antisepsis in obstetrics, 587.
Aseptic operating, 427.
Asphyxia, a case of so-called traumatic, 226.
Association of Medical Librarians, 902.
Asthma, diagnosis of bronchial, in children, 176; nasal treatment of, 17; nervous, and skin diseases, 821; relation of ethmoidal inflammation to, 855.
Astigmatism, observations upon, 66.
Atherton, A. B., a case of cicatricial stricture of the esophagus, 376.
Athletic games, injurious effects of, 780.
Athletics, use and abuse of, 65.
Atrichia, a case of universal congenital, 709.
Atropine in inebriety, 228.
Atwood, Charles E., a case of heroine habit, 856.
Aural examination, the importance of, in acute diseases of children, 67.
Australasian Medical Congress, 303.
Axilla, care of the, after operations on the, 34.
Ayer, J. C., a study of fifteen cases of erysipelas, treated by injections of antistreptococcus serum, 325.

B.

Back, importance of physical examination of the, 467.
Bacteriology of the Egyptian deserts, 418.
Bailey, John H., cryoscopy of cerebrospinal fluid in epidemic cerebrospinal meningitis, 215.
Ballenger, E. G., a review of some recent papers on the surgical treatment of prostatic hypertrophy, 166.
Bandler, appointment of Dr. Samuel W., 862.
Bangs, L. Bolton, etiology of enlarged prostate, 524; presentation of the portrait of Dr. Fessenden Nott Otis to the Academy of Medicine of New York, 657.
Barkan, Louis, calcium sulphide in diabetes and gingivitis, 586.
Barker, a dinner to Dr., 861.
Barker, Dr. Lewellys F., election of, 542.
Barlow's disease, a case of, 949.
Barnes, Justin L., removal of the lens in myopia, 925.
Baruch, Simon, Geheimrath, Dr. Dettweiler, 225.
Bashore, Harvey B., sanitation of the summer camp, 777.
Beards, an edict against, 863.
Beck, Carl, an abdominal spoon, 200; on some relations of medicine and surgery to jurisprudence, 209.
Becquerel rays, influence of, on the skin, 118.
Bellevue Hospital, appropriation to build new, 462; the new, 901.
Berg, Henry W., the present limitations of serum therapy in the treatment of infectious diseases, 689.
Beriberi, 140; at the St. Louis Exposition, 822.
Berlin, letters from, 144, 266, 425, 627, 785, 981.
Biceps, flexor cubiti, rupture of the, 950.
Bile, elimination of, 591; pigment, a simple test for, 311; toxicity of the, 837; tract adhesions, 447.
Bile duct disease, certain aspects of, 385.
Biliary drainage in operations on the gall bladder, 194.
Biliousness, the hepatic factor in, 670.
Bill, a remarkable, 660.
Biological station, a marine, 822.
Birth rate and postponement of marriage, 581.
Birth rates, general death rates and death rates from cancer for the New England States for the year 1900, 307.
Black list, legislative action sought against a, 222.
Black water fever, salts of potassium as a prophylactic for, 379.
Bladder, extrophy of the, 557.
Blaud's pill, a new form of, 550.
Blind, employment of the, in massage, 114.
Blindness, hysterical, 230.
Blood, action of the *x*-rays on the, 350; differentiation of, of related animals, 428; effect of high altitudes on the, 349; examination in surgical diagnosis, 452, 478; observations upon the, 787; occult, in the feces, 954; plasma, relationship of the proteids of the, 551; pressure, treatment of high, 314; serum, reaction of, human, 110; tests, forensic, 509; viscosity of the, in disturbances of carbon dioxide elimination, 709.
Boggs, Russell H., the present status of Roentgen-ray therapy, 693.
Boldt, H. J., a vermiform appendix invaginating probe, 118.
Bone and joint diseases in children, symptoms of, 137; cavities, treatment of, 827; transference, 390.
Bones, articular surfaces of the long, as a characteristic of sex, 341.

Bourbon County Medical Society, 144
Bovaird, Jr., David, a review of the recent literature on the relation of human and bovine tuberculosis, 283.
Bowels, splindle-cell sarcoma of the, operated on successfully, 217.
Bradycardia, an unusual case of, 617, 983.
Brain, delayed results of a wound of the, 146.
Brains of eminent men, to secure, 22.
Brewer, George E., a report of, 84; operations on the kidney and ureter, 241.

Briggs, John Bradford, a recent epidemic of typhoid fever, 7.
Bronchitis, chronic, as influenced by a change of climate, 705.
Bronx Valley sewer, 863.
Browd, E. K., the use and abuse of curettage of the uterus, 131.
Brown tail moth eruption, 146.
Bryant, Alice G., the importance of early recognition of suppurative ear disease, 731.
Bryant, W. Sohier, the front bent gouge in cranial surgery, 798; the value of the present quantitative tests for hearing, with the demonstration of a new apparatus, 489.
Bubo, notes on climatic, 458.
Bubonic plague, suspected cases of, 180.
Buchanan, J. J., the advantages of performing capital operations in selected cases without anesthesia, 289.
Bulkley, Dr. L. Duncan, a course by, 222; dermatitis seborrhoica and its relations to alopecia and other conditions, 726.
Bull, Chas. Stedman, the treatment of inoperable cases of malignant disease of the orbit by the *x*-ray, 961.
Bull, William T., results of 1,500 operations for the radical cure of hernia in children, performed at the Hospital for Ruptured and Crippled between 1891 and 1904, 401.
Bullet embedded in the middle ear, radical operation for the removal of, 374.
Burial, prevention of live, 581.

C.

Cab drivers' mortality record, 102.
Cactus grandiflorus, 857.
Calcium, chloride in nasal hemorrhage, 467; sulphide in diabetes and gingritis, 586.
Calculi, diagnosis of renal and ureteral, 171.
Calculus, primary urthral, 390.
Calomel as an intestinal antiseptic, 79.
Camphor and digitales, 270.
Camphor poisoning, 869.
Camphorated naphtol, dangers of injections of, 350.
Canal, earlier conditions of the, 189; problems, 188; zone, health of the 662; sanitation in the, 221.
Cancer, 869; a clinic on, 342; and cirrhosis of the liver, 351; and carcoma in the same patient, 670; arising after twenty years in a vaccination scar, 800; chemical features of, 310; cinnamic salts in the treatment of, 788; death from, 22 years after primary operation, 670; etiology of, 788, 590; germ cell, theory of, 28; growth of 589, 939; humane treatment of, 146; in men and women, 163; in the mouth, 628; Kelling's serum, reaction in, 828; lunus, 861; morphology and etiology of, 29; mortality from, 859; of the appendix, 437; of the breast, mechanism of propagation of, 70; of the breast relieved by *x*-ray therapy, 110; of the cervix, treated by radiotherapy, 911; of the penis, treated by the *x*-ray, 435; of the stomach, obscure cases of 898; of the stomach, results of surgical treatment of, 146; of the tongue and neck, 507, 232; of the uterus, *x*-ray treatment in, 426; origin and treatment of, 877; presence of plasmodiophoral in, 269; serum, another, 100; the cure of, 669; the etiology of, 699; the nature of, 630; views, 422.
Candy, adulteration of, 382.
Cannaday, J. E., gunshot wounds of the abdomen, 895.
Canteen, the army, 145.
Carbolic acid, dry gangrene following the application of, 226.
Carbon dioxide, absorption of, from the stomach, 458.
Cardiac, collapse during examination of a post pharyngeal abscess, 65; dilation, acute, 388; insufficiency, causes of, 119.
Cardioptosis and enteroptosis, cases of, 628.
Cardiospasm, treatment of, 796.
Carstens, J. H., spleenless men, 11.
Carter, William Wesley, growth of bone in the tonsil, 174.
Cartilage, healing of, in wounds, 271.
Caseins, digestion of, and its relation to infant feeding, 321, 355.
Cataract, extraction of, 190; treatment of infections following operation for, 230.
Cataracts, scissors for cutting secondary membranes, 718.
Catching cold, 178.
Catgut, I. K. I. method of sterilizing, 267.
Catharsis, the bacterial element in, 947.
Cathartics, dangers from, in acute intestinal conditions, 347.
Cats, fear of, 792.
Cecum, tumor of the, with intestinal anastomosis, 632; volvulus of the, 229.
Census, a new, 303.
Ceonothus velutinus, poisoning by, 753.
Cephalocele occipitalis inferior, 75.
Cerebellar abscess, 67; seizure, a characteristic syndrome, 267; tumors, diagnosis of, 267.
Cerebellum, cyst of the, 350; functions of the, 267.
Cerebral hemorrhage, non-traumatic in a child, 309; relation of, to atmospheric conditions, 369.
Cerebral palsies in children, 26; syndrome, post-malarial, 390; tumor, spontaneous recovery from a, 20.
Cervical rib, with symptoms resembling subclavian aneurysm, 551.
Cervix, methods for rapid dilatation of the 549.
Cesarean section for congenital malformation of the cervix, 828; seven cases of, 797.
Chancre of the lip, four cases of, 290.
Chapin, Henry Dwight, standardized gruels; an application of the percentage principle to gruel feeding, 246.
Chest and abdomen, perforating bullet wound of the, 556.
Chicago, a scared commissioner in, 141; charity ball, 102; Medical Examiners' Association, 22; Medical Society, business bureau of the, 501; mortality in, 861; Pediatric Society, 863.
Child labor law, amendment to the, 821.
Child study and paralysis in children, 148.
Chloroform, relations between arterial pressure and absorbed doses of, 428.
Cholecystitis in the puerperium, 532; as a complication of pneumonia, 467.
Cholemia and uremia, nature of, 837.
Cholera Congress in Russia, 582.
Cholera, protective inoculation against Asiatic, 260.
Chorea, 268; an unusual case of, 392; ergot and arsenic in, 349; fatal, from excessive muscular action, 706; mental states in, 109; successfully treated with apomorphine, 426; treatment of, by warm baths, 27.
Choroiditis due to necrosing ethmoiditis, 676.
Chorioepithelioma malignum, 674.
Christian science dupes must pay their own damages, 220; status of, in Ohio, 380; test of, 180.
Christian scientists not seeking to come within the law, 462; recognition of, 38.
Chromhydrosis, a case of, 69.
Chronic dyspepsia due to defective drainage and gastric atony, surgical treatment of, 229.
Chylous ascites, 115, 867; with eosinophibia, 308.
Chylous cyst of the abdomen, 267.
Cigarettes, against, in Wisconsin, 463; a tax on, 264; legislation against, 660.
Cincinnati Academy of Medicine, 263, 423, 463, 502, 584, 781, 803.
Cincinnati health reports, 102; Medical Library Association, 180; Society of Medical Research, 142, 222.
City hospitals, appropriations for, 302.
Civil service, examinations, 462.
Climates, therapeutic value of relaxing, 580, 858.
Club foot, diagnosis of non-deforming, 106.
Coal gas poisoning, lesion of the lenticular mucleus found in, 436.
Cocaine habit in Washington, 22; habituation among negroes, 623; legislation to restrict sale of, 263.
Coe, Dr. Oliver P., appointment of, 62.
Coe, W. H., an unusual case of pelvic abscess, 291.
Coggeshall, Henry, the relation of ethmoidal inflammation to asthma, 855.
Coley, William B., results of 1500 operations for the radical cure of hernia in children, performed at the Hospital for Ruptured and Crippled between 1891 and 1904, 401.
Colitis, and appendicitis, relationship between, 469; mucous, 698.
Collections, hospital Saturday and Sunday, 661.
College of Physicians of Philadelphia, 62.
Collins, Joseph, multiple myeloma (Kahler's disease). A contribution to its symptomatology and its morbid anatomy, 641.
Colon bacillus, infection simulating uremia, 827; toxin, reaction of, 861.
Columbia's graduating class, future pursuits of, 941.
Columbus Hospital at Chicago, 380.
Commissions, resolutions on, 542.
Communion cup, dangers of the common, 311.
Comroe, Julius H., an unusual case of bradycardia, 617.
Condensed milk, cause of gas fermentation in, 156.
Confessionals, disinfection of, 262.
Conjunctional, irritation from animal emanations, 908; bacteriology, practical aspects of, 508.
Conjunctivitis, a case of Parinaud's, 389.
Connecticut Medical Society, 902.
Connell, F. Gregory, definition and classification of gastric hemorrhage, 15.
Consent of patient before operations, 302.
Constantinople, letters from, 305.
Constipation, 640; a case of long standing, 349; a test for, 69; rational treatment for chronic, 159; treatment of chronic, 589.
Consumption, is it curable? 300; to check the spread of, 542.
Consumptive teachers barred from public schools, 181.
Consumptives, menace of traveling, 819; national fraternal sanitorium for, 382; proposed city hospital [illegible] 2.
Convulsions and paralysis, two cases of, in young subjects, associated with exudative erythema, 909; in children in relation to epilepsy, 68.

Convulsive tic, 268.
Continuous current in relation to inflammatory exudates, 114.
Contract work harmful, 542.
Copper, foil, efficiency of, in destroying typhoid and colon bacilli in water, 305; in canned foods, 134; salts in the purification of water supplies, 459; sulphate alone and in combination with lime for the destruction of mosquito larvæ, as deodorant and distinfectant, 90, 152.
Corneal opacity, transverse ribbon-shaped, 673.
Coronary arteries, sclerosis of the, 751.
Coroner system, the end of the, 501.
Coroner's bill, 358, 622.
Corpora lutea, mitosis in the, 632.
Correspondence, Berlin, 144, 266, 425, 627, 785, 981; Constantinople, 305; Kobe, 425; London, 3, 63, 104, 143, 182, 265, 224, 304, 344, 385, 424, 464, 504, 544, 584, 625, 664, 704, 744, 784, 824, 864, 906, 945, 980; Manila, 62, 224, 265, 505, 543, 585, 624, 745, 866, 982; Paris, 183, 305, 466, 665, 865; Vienna, 105, 384, 545, 666, 825.
Cortical cirrhosis, diffuse, 316.
Coryza, treatment of, 428.
Cottam, Gilbert G., compound traumatic separation of the lower epiphysis of the femur, 487.
Couch, Louis B., formic acid in rheumatic conditions, 972.
Coughing, modifications of the pulse under the influence of, 230.
Coughlin, Robert E., use and abuse of athletics, 65.
Coughs and colds, 338.
Counting chamber, a new form of, 869.
Coxa vara and its differential diagnosis, 233.
Craniotomy, is it ever justifiable on the living child? 395, 893.
Crawcraw, in England, 57.
Cream cakes, poisoning due to, 830.
Cretin, precocious puberty in a female, 310.
Cretinism, important differential points in the diagnosis of, and alied conditions, 914.
Criminal abortion, 632.
Crothers, T. D., the army canteen, 145.
Cryoscopy in renal disease, 274.
Cryptorchidism, a case of, 145.
Cuba and Panama, sanitary conditions encountered in, 161, 189; quarantine against, 582; sanitation of, 62, 233.
Curettage of the uterus, use and abuse of, 131.
Cushion diseases, 896.
Cuspidors for rapid transit stations, 343.
Cutaneous syndrome of gastrointestinal origin, 911.
Cutting instruments, sterilization of, 840.
Cycloplegics, to what extent are they necessary in determining the refraction of the eye? 193.
Cystitis, ascending paralysis in chronic, 508.
Cystoscopy, 346; and renal lavage, 761.
Cystoscope, and internal catheter, 36; in genito-urinary surgery, 146.
Cystotomy, some points on suprapubic, 673.
Cysts of the maxilla, Partsch method in, 110.

D.

Dairy hygiene, 107.
Damage suits, bill to prevent the solicitation of, 463.
Dartmouth Medical Alumni, 863.
Davis, Dr. Albert A., 823.
Davis, memorial tablet to Dr. N. S., 501.
Deafness, operation for catarrhal, 909.
Death rate, lower, 382.
Death, sudden, in children from a surgical point of view, 418.
De Garmo, W. B., tuberculous testicle and the *x*-ray, 576.
Degrees at Columbia, new requirements for, 422.
Delavan, D. Bryson, primary epithelioma of the epiglottis, 698.
Delirium as a symptom of hysteria, 386.
Dementia praecox, and allied states, 277.
De Mund, John T., treatment of cerebrospinal meningitis, 586.
Dengue in the canal zone, 147.
Dental diseases, relationship of to other diseases, 669.
Dentist, suicide of the Kaiser's, 101.
Dentition, as a factor in the etiology of epilepsy, 300; medical aspects of second, 948.
Department of Health, a new, for Pennsylvania, 783.
Dermatitis seborrhoica, and its relation to alopecia and other conditions, 193, 726.
Dermatoses, treatment of, by radium, 400.
Dettweiler, foundation, a, 342; Geheimrath, Dr., 225; Geheimrath, Dr., presentation of a portrait of, 136, 156.
Diabetes, after operation, 28; complications of, 100; loaf sugar in, 948; of infectious origin, 949.
Diabetes mellitus, 899; relation of stomach disorders to, 795.
Diaphragm, eventration of the, 710.
Diathesis and allied conditions, 547.
Diazo reaction, value of, in typhoid fever, 309.
Dickinson, Robert L., system and expedition in office practice. Office plans and details, 681.
Diet after the age of one year, 227.
Digestive disturbances, 920.
Digitalis, delirium and halucinations of, 507; poisoning, a case of, 786.
Digestion, advances in the knowledge of the chemical processes of, 952; disturbances of in infants, due to too high fat percentages, 66.
Digestive disorders, treatment of, 51.
Diller, Theodore, a case of long standing major hysteria characterized by a paroxysmal and fixed pain, mental depression, confusion, delirium with delusions, and halucinations terminating in sudden recovery, 736.
Diphtheria, arterial pressure in, 188; bacilli, morphology of, 509; defense against, 541; dichondra as a bactericide in, 335; epidemic of in the Willard State Hospital, 620; extensive cutaneous, 748; infection in Minnesota, 154; laryngeal, 879; on Staten Island, 222; poison, dialyzed, 427; the rapid bacteriological diagnosis of, 492; the treatment of, 820.
Diphtheritic paralysis, 800.
Diplomas withheld, 942.
Disinfection and disinfectants, 152.
Dispensary system, New York's, 421.
Dissecting room material, a source of, 382.
Dissociation of sensibility, pathogenesis of, 429.
Doctor and patients, long association of, 141.
Doctors—are they observing? 219.
Dogs, use of ambulance, in war, 178.
Doty, A. H., the use of sulphate of copper alone, and in combination with lime, for the destruction of mosquito larvæ, as a deodorant, and as a disinfectant, 90.
Douglas, Charles J., the physician's aim, 466.
Dourine, the trypanosoma of, 483.
Drowning, proof of death by, 590.
Druggists, new excise laws for, 902.
Drugs, adulteration of, 747.
Duodenal ulcer, 29.
Dust and patent medicine advertisements, 386.
Dust, beneficent, 820.
Dysentery, etiology and serum treatment of, 955; treatment of, by irrigation of the colon, through the vermiform appendix or an opening into the cecum, 455.
Dyspepsia, 947.

E.

Ear, apparatus for applying hot air to the, 707; disease, importance of early recognition of suppurative, 731; non-suppurative disease of the, leading to deafness, 992.
Earth temperature and diarrheal diseases in Dublin, 911.
East Side Physicians' Association of New York, 21.
Eating, the art of properly, 5.
Eclampsia, 618, 680; etiology of, 708; hemorrhages in, 389; modern theories of, 70; of intestinal origin, 187.
Eczema, as a complication of senility, 629; treatment of, in children, 768.
Edema, remarks on, 868.
Edinburgh Medical Journal, centenary of the, 261.
Einhorn, Max, the art of eating properly (euphagia) and the harm of eating too rapidly and too slowly (tachyphagia and bradyphagia), 5.
Elbow joint, excision of for traumatic and arthritic aukylosis, 72; treatment of aukylosis of the, 69.
Electric light bulbs, phenomena produced by rubbing, on the skin, 509.
Electric potential, value of, in electrodiagnosis, 591.
Electricity, high frequency in the treatment of surgical diseases, 34.
Electro-therapeutics, advance in, 546.
Ellingwood, Finley, cactus grandiflorus, 857.
Embolism, following surgical intervention, sudden death from, 47.
Emmett, a dinner in honor of Dr., 861.
Emphysema, interstitial, of the lung, 520; subcutaneous, in asthma, 187.
Empyema cured without operation, 274; treated by Perthes' method, 827.
Encephalomeningocele, 891.
Endocarditis, a case of, due to the micrococcus of gonorrhea, 508; fever in chronic, 793.
Endothelioma, spontaneous arrest of growth in, 109.
Enemata, prolonged use of, 187.
English medicine in the Anglo-Norman period, 58.
Enterectomies, condition of the intestines after, 707.
Enterectomy at twelve hours of age, 589.
Enterocolitis in the tropics, 350.
Enteroptosis and cardioptosis, cases of, 628.
Enterostomy, 587.
Enuresis, treatment of, 65.
Epididymitis, due to the typhoid bacillus, 350.
Epigastric pains, significance of, 628.
Epiglottis, primary epithelima of the, 698.
Epilation, a new method of, 388.
Epilepsy, 756; and hysteria, differential diagnosis between, 746; autopsy findings in, 706; care and cure of, 235; dentition as a factor in the etiology of, 300; eclampsia and kindred disorders, relation of the internal secretions to, 227; nature and treatment of, 548; prognosis of, 240, 307; treatment of, 507.
Epileptic, criminal, the, with report of two cases, 295; the State's relation to the, 225.
Epithelial tumor of the inguinal region, 350.

Equinovarus, results of operation for, 714.
Ergot, prophylactic use of, during labor, 187.
Erysipelas, fifteen cases of, treated by antistreptococcus serum, 325; with an excessive production of fibrin, 615.
Erythema, induratum, treatment of, 75; infectiosum, 108; nodosum, etiology of, 28.
Esophageal pouch treated by excision, 630.
Esophagoscope, use of, in diagnosing and removing foreign bodies from the esophagus, 470.
Esophagus, benign strictures of the, 747; cicatricial stricture of the, 376; dilatation of stenosis of the, through the esophagoscope, 590; distention of the, for removal of a foreign body, 470; diverticula of the, 952; foreign bodies in the, 185, 830; removal of foreign bodies in the, 808.
Essential metrorrhagia, hysterectomy for, 633.
Essex Medical Society, 822.
Ether, explosion in a hospital, 302; narcosis by rectum, a method of producing, 617.
Evans, T. H., the epileptic criminal; with report of two cases, 295.
Exanthemata, alkalinity of the blood in the, 960.
Ex-Christian Scientist, an, 942.
Exophthalmic goiter, antithyroidin in, 149, 557, 820; combination of excision and *x*-ray treatment for, 909; four cases of, in one family, 313; in a child, 315; iodized gelatin in, 591; parathyroid therapy in, 827; pathology of, 838; three cases of, treated with the blood of thyroidectimized sheep, 790; two cases of, 385.
Exophthalmos intermittent, 309.
Eye-glasses, the purpose of, 506.
Eye lesions of chronic lead poisoning, 69.
Eyelid, tumor of the, treated with radium, 913.
Eye muscles, rheumatism in the, 193.
Eyes and ears of public school children in Vermont, examination of the, 221.
Eyesight, defective, of New York school children, 782.
Eye strain, 345, 669, 748.

F.

Facial neuralgia, extirpation of the Gasserian ganglion in, 34.
Faciohypoglossal nerve anastomosis, 477; special instruments for, 359.
Family physician, the, 196.
Fat, embolism after fractures, 347; necrosis, experimental observations on, 671; necrosis, extensive, with involvement of the pancreas, 472; question, the, in its relation to infantile marasmus, 914.
Fatigue, albuminuria and glycosuria from, 830.
Fatty degeneration, pathology of, 600.
Faught, Francis Ashley, the prosthetic treatment of fracture of the mandible, 332.
Fecal tumor simulating fibroma, 748.
Fedde, B. A., the conduct of the perineal stage in normal labor, 655.
Feeding subcutaneously, 790.
Feet, painful affections of the, 95.
Femora, rachitic fracture of the, 75.
Femur, chronic osteomyelitis of the, treated by iodoform wax filling, 476; compound traumatic separation of the lower epiphysis of the, 487; treatment of fracture of the neck of the, 677.
Fenger, memorial bust of Dr., 222.
Fetal, development, three cases of excessive, 10; [illegible] of determining the level of the, in the pelvis, 709.
Fever, a new theory of, 599; in children, 408; nervous [illegible] of, 671.
Fibroid tumors of the uterus, when to operate for, 754.
Fibrosarcoma, a large, treated by *x*-rays, 258.
Field, A. G., a new [illegible], 919; bloodletting in cerebrospinal meningitis, 784.
Fiboriasis cured by removal of the adult worms, 778.
Filters, permeability of, 235.
Finsen, method, the, 26; memorial fund, 702; treatment, bactericidal action of light in the, 709.
First aid, journal devoted to, 180.
Fissure in ano, etiology of, 886.
Flatfoot, new operation for, 747.
Flies and enteric fever, 378.
Flint, Carlton P., traumatic rupture of the intestine without injury to the abdominal wall, 248.
Floyd, Rolfe, erysipelas with an excessive production of fibrin, 615.
Fluorescence, of the urine in diabetes, 800; therapeutic uses of, 548.
Fluke, a new Asiatic blood, 827.
Food adulteration, 623.
Foreign body in the bronchus removed with the bronchoscope, 217.
Formaldehyde, 900; as a preservative for urine, etc., 671; onychia, and dermatitis, 270; the toxic effects of, 419; war, 622.
Formic acid in rheumatic conditions, 972.
Forty, something accomplished after, 421.
Foster, a luncheon to Dr., 20; jubilee to Dr., 17.
Fowler, H. G., the diagnosis of renal and ureteral calculi, 171.
Fractures, and sprains, operative treatment of, 72; rational treatment of, 310; epiagraphy in the treatment of, 73; treatment of compound, 754.
Fraenkel, Joseph, the relation of the nervous system to visceral and trophic phenomena, 481.
Frontal sinuses, lymphosarcoma of the, 480.
Frontal sinusitis, suppurative, 270.
Front bent gouge in cranial surgery, 798.
Fundus oculi, photography of the, 350.
Furuncles and carbuncles, a new local treatment for, 949.
Fusiform bacillus, differentiation of, from the spirillum sputigenum, 501.

G.

Gall-bladder, cancer of the, due to gallstones, 228; and appendix, anatomical peculiarities of the, 827; infection of the, 53; rupture of, 440; symposium on diseases of the, 753.
Gallia County Medical Society, 783.
Gallstones, and cancer, 707; in the common duct, 879.
Gallstone disease, effects and treatment of, 706; 1000 operations for, 550.
Gallstone obstruction of the bowels, 786.
Galvanism in nervous diseases, 716.
Garcia celebration, the, 461.
Garcia, Manuel, centenary jubilee fund, 101; teacher, discoverer and man, 441.
Garcia memorial fund, 583.
Gardener's spade deformity in fracture of the radius, 808.
Garfield, President, at Elberon, 112.
Gas, deaths by illuminating, 623.
Gastric, area, determination of the, 954; digestion, meat extractives in relation to, 870; efficiency, a new test of, 770; fistula, spontaneous, 560; hemorrhage, definition and classification of, 15; hemorrhage, treatment of, 506; secretion, effect of biliary retention on, 952; tetany, 91.
Gastritis, experimental, 429; treatment of, 428.
Gastroenterostomy, 184; posterior, by Murphy button or triangular suture, 557.
Gastrointestinal diseases of children, 878.
General paralysis, recent observations on, 311.
Genu valgum and genu varum, two hundred osteotomies for, 108.
Germ, a blue, 583.
German Association of Naturalists and Physicians, 978.
Giemsa's stain, 280.
Gilbert, J. Allen, the subconscious self, 93.
Glanders, human, 753.
Glasgow's isle of drunkards, 105.
Gleitsmann, J. W., intratracheal injections, 449.
Glucose enemas in diabetes, 59.
Gluttony or "food poisoning" as a cause of epileptic convulsions, 134.
Glycogen content of the liver, 150.

Hunt, J. Ramsay, intermittent claudication and allied syndromes due to angiosclerosis of the extremities, 801.
Hunter, Jr., James W., the treatment of digestive disorders, 51.
Hutchinson, Woods, let the lungs alone in consumption, 645.
Hydrocele in the female, 950.
Hydrochloric acid in the gastric contents in malignant disease of organs other than the stomach, 748.
Hydrotherapy, mistakes in, 708.
Hymen, histology of imperforate, 230.
Hypertension, early recognition of, 107.
Hyperpyrexia, cold affusion in, 670; hydrotherapy in, 630.
Hypochondriasis, 69.
Hypodermoclysis, 946.
Hypophysis, studies of the, of castrated animals, 671.
Hyoscine, in the treatment of morphinomania, 753; morphine narcosis, 590.
Hysterectomy, effect of on the sexual functions, 26; for fibroids, with report of 250 operations, 629; vaginal, for chronic inflammatory conditions, 634.
Hysteria, a case of long-standing major, 736.
Hysterical movements, 268.

I.

Ideals and practices of the medical profession, 958.
Iliocecal invagination, 351.
Illinois, bills of medical interest in, 422; board of health, 303; medical legislation in, 781; Medical Society, 822; sanatorium for consumptives, 381; State Medical Society, 863.
Illness, a costly, 98.
Illuminating gas, dangers of, 997.
Immigrants, inspection of, 341.
Immigration, legislation, medical phases of, 932; problems of, 620; service, needs of the, 180.
Immunity, and infection, symposium on, 712; local, of the tissues, 709.
Impetigo, treatment of, in children, 768.
India, plague in, 742.
Indian girls as nurses, 263.
Indol test, improvement in technique of the, 156.
Indormescent shocks, 957.
Indoxyl, in the urine as a sign of melancholia, 901.
Incubator exhibits, a bill to stop, 303.
Inebriates, hospital-jail for, 741.
Infancy, feeding in, 185.
Infant feeding, 867; by nurses, 155; difficulties in artificial, 752; in relation to the digestion of caseins, 321, 355.
Infantile paralysis, epidemic, 461.
Infants, digestive disturbances, due to excess of fat in mother's milk, 830.
Infection, sources of, 153.
Inflammatory conditions, treatment of with aspirating apparatus, 748.
Influenza, 788; bacilli, respiratory infections with, and their relations to tuberculosis, 826; complications of, 878.
Insane, suggested improvements in the care of the, 863; what the State of New York is doing for the, 668.
Insanity, forms of due to alcohol, 268; increasing in Connecticut, 141; prevention of, by the general practitioner, 907; the genesis of, 16.
Insects, suctorial, as plague-carriers, 551.
Interesting case, report of an, 618.
Intermittent claudication, and analogous phenomena, 279; due to angiosclerosis of the extremities, 801; two cases of, 514.
Internal secretions, the relations of, to epilepsy, eclampsia, etc., 227.
International Congress of Medicine, fifteenth, 502.
Intestinal anastomosis, a soluble button for, 588; by the Connell suture, 175; obstruction, treatment of, 750; paresis, treatment of, 785; perforation, 346; worms, pathogenic action of, 870.
Intestine, an undescribed form of ulceration of the large, 920; traumatic rupture of the, without injury to the abdominal wall, 248; treatment of hemorrhage of the, 552.
Intramuscular hemorrhage from muscular action, 163, 191.
Intrapleural lipoma, 792.
Intratracheal injections, 449.
Intrauterine amputation, 914.
Intussusception, acute, in an infant; resection; recovery, 334; and a new method of operation, 789; in an infant, 556.
Inverted position, dangers of, in operations on the uterus, 789.
Iodic acid and the iodates, clinical uses of, 228.
Iron ring from human blood, an, 498.
Isaacs, A. E., decapsulation of the appendix, 574.
Ischochymia, and its treatment, 907, 953.
Isthmian Canal Zone, diseases of the, 41.

J.

Jackson, George T., acne and its treatment, 408.
Japan, medical education in, 56.
Japanese, army medical service of the, 100; army ration, 320; hospital ships, 408; naval casualties, statistics of the, 60.
Jarecky, Herman ear complications of scarlet fever and their treatment, 292.

Jaundice, intestinal putrefaction in, 310.
Jaw, tumor of the, treated with radium, 913.
Jejunium, volvulus of the, 390.
Johnson, Frank M., cystoscopy and renal lavage, 761.
Joliet (Ill.) Penitentiary, sanitary condition of the, 622.
Jones, Mary A. Dixon, difficulties in microscopical work in smoky cities, 667.
Journal of Experimental Medicine, the, 463.
Jurisprudence, relations of medicine and surgery to, 209.

K.

Trypanosomiasis, chrysoidin in, 68; experiments in the treatment of, 909.
Tubal pregnancy, diagnosis of, 75.
Tubercle bacilli, effect of on growth of colon bacilli, 578; homogenized cultures of, 668.
Tubercle bacillus, feeding with the essential fat of the, 352.
Tuberculosis, 507; abdominal, 629; administrative control of, 594; among negroes, 781; and adaptation, 706; a new double strain of the bacillus of, 184; a new remedy for pulmonary, 497; a sanatorium on wheels for the treatment of, 660; attempts to find a specific remedy for, 830; a working program for associations for the prevention of, 834; bacillus of, in the blood, 750; bacillus of, in man and animals, 153; bill vetoed in Pennsylvania, 582; bovine, 740; city's clinic for,

582; climatic treatment of, in Colorado, 957; commission of Vermont, report of the, 140; comparison of *x*-ray and surgical treatment of, 107; diet in pulmonary, 250; directory, 142; dispensary cures of, 978; early diagnosis of pulmonary, 303, 888; etiology of pulmonary, 184; exhibition, a, 821; experimental, of the heart and aorta, 359; fresh-air treatment of surgical, 157; from the layman's point of view, 833; healing of, 11; heart and circulation in pulmonary, 851; hemoptosis in, 510; Illinois State Association for the prevention of, 141; immunization against, 229; in Boston, 263; in cold-blooded animals, 187; influence of habitation on, 539; in Indiana, 901; in Japan, 66; in Joliet penitentiary, 582; in prisons, 579; in tenement districts, 21; intrapleural complications in pulmonary, 307; is pulmonary, a menace to the health of Los Angeles? 752; Missouri State sanatorium for, 462; mixed infection in pulmonary, 958; morphology and classification of the bacillus of, 346; of the elbow, resection and iodoform wax filling, 556; of the gastrointestinal tract, 427; of the larynx, treatment of with sunlight, 187; open-air treatment at home for, 438; passage of agglutinins and antitoxins into milk, 710; politico-sociological aspects of, 746; primary, of the breast, 467; problem and the home, 377; problem in Illinois, 957; pulmonary and climates, 975; recent investigations regarding, 419; relation of the medical profession to the restriction of, 770; renal, 311; report of committee on, 154; review of the recent literature on the relation between human and bovine, 283; sanatoria, 309; sanatorium, bill for, vetoed, 822; sanatorium, opposition to, 862; situation in penal institutions, the, 721; specific therapy of, 547; sugar in the treatment of pulmonary, 429; symposium on, 872; tape worm, cure for, 583; the heart in, 752; theory, observations on children relative to von Behring's, 187; treatment of, 959; treatment of pulmonary, among negroes, 941; vaccination against, 911; value of diazo-reaction in pulmonary, 429; value of publicity regarding, 44; value of rales as a sign of, 826.

Tuberculous, adenitis, treated by the *x*-ray, 440; cows, milk of, 470; insane, tent treatment for the, 460; patients, the cardiac area in cured, 671; synovitis, treated by *x*-rays, 269.

Tumor, intracranial, followed by cerebrospinal rhinorrhea, 707.

Tuning fork in physical diagnosis, the, 640.

Turbinate, cauterization of the lower, 25; the middle, in sinus disease, 197.

Turning in walking, the mode of, as a diagnostic sign, 60.

Turpentine poisoning, acute, 467.

Twine triangular stitch for intestinal operations, 557.

Typhoid bacilli, enhancing the agglutinating power of, 470; bacilli in relation to vegetables, 150; bacilli, persistence of agglutinability in, 156; coxitis, 268; immunity, nature of, 349; serum, agglutinating power of, for paratyphoid and allied organisms, 220.

Typhoid fever, 347; a case of presenting unusual features, 309; a curative serum for, 787; and pregnancy with reference to fetal infection, 948; a recent epidemic of, 7; bisulphate of sodium in the treatment of, 679; bone marrow in, 578; cardiac and vascular complications and sequels of, 99; copious water drinking in, 388; death in operated cases of perforation in, 26; diet in, 747; diminished by water filtration, 62; elimination of, 588; Ficker's method of diagnosis in, 229; from infected ice cream, 661; general septic peritonitis in, 787; hemorrhagic, 180; in camps, 667; in children, six cases of perforation in, 794; in infancy, 741; in New York, 859; inoculation against, 659; in Philadelphia, 501, 541; in relation to the urban and rural population, 669; in Winnipeg, 222; perforation in, 548; prevalence of, in Philadelphia, 462; polyneuritis complicating, 26; protective inoculation against, 829; recent epidemic of, 176; symposium on, 752; the existence of, in Bermuda, 708; throat complications in, 520; treatment of, 138; treatment of by tincture of iodine, 591; unusual features in the recent outbreaks of, 192; vegetative endocarditis in the course of, 552.

Typhoidal insanity in childhood, 389.

U.

Ulcerative processes, a new remedy for, 497.

Ulcers, treatment of varicose, 428.

Uncinaria duodenalis and strongyloides intestinalis, double infection with, 432.

Uncinariasis in California, 753; in Porto Rico, 779.

United States Army and its medical corps, our duty to the, 74.

University, the largest, 351.

Uremia, necrosis of the liver in, 749.

Urethritis, iodide of silver in, 911.

Ureteral meatoscopy, 273.

Uric acid, its influence on gout, 426.

Urinary tract, newer aids to diagnosis in diseases of the, 32.

Urine, a contact method for testing, 639; examination of the, 507.

Urticaria, a case of menstrual, 738; nature of, 149.

Utah State Medical Society, 979.

Uterine adnexa, inflammatory disease of the, 841; displacements, 676; fibromyoma with vesical troubles, 552.

Uterus, accidental rupture of the nonparturient, 989; a new method of suspension for retrodisplacements of the, 673; an undetermined tumor in the, 395; fibroid tumor of the, 115, 426.

Uvula, primary epitheloma of the, 706.

V.

Vaccination, accidental, 108; compulsory, not unconstitutional, 342; law, the California, upheld, 460; protective power of, 630; results, Canadian, 360; shield, a multiple, 780.

Vaccine bodies, the nature of, 214; production of animal, 155.

Vaginal cesarean section, a case of, with recovery, 417; hysterectomy, latero-vaginal incision in, 110.

Vaginalitis, bacteriology of, 110.

Vale Osler, 819.

Van Arsdel, E. B., report of an interesting case, 618.

Van Dyke, F. W., higher education a cause of physical decay in women, 290.

Van Zandt, I. L., saw palmetto, 937.

Varicella, an unusual complication of, 549.

Varicose ulcers, peroxide of zinc in the treatment of, 520; veins, treatment of by walking, 350.

Variola, 588; hybrida, 58.

Vaso dilators and constrictors, 146.

Vasomotor disturbance, a case of, caused by sunlight, 191.

Vater's diverticulum, duodenal orifice of, 502.

Venereal diseases, prophylaxis of, 293, 308.

Vesical calculus, varicose veins in the bladder in reference to, 110; disturbances, the prophylaxis of after gynecological operations, 640.

Vermont Board of Medical Examiners, 101.

Vibrating sensation in nervous diseases and diabetes, 588.

Victoria, operation on Princess, 179.

Vienna, letters from, 105, 384, 545, 666, 828.

Village without a doctor, 102.

Vincent's angina, clinical and bacteriological status of, 595; symptomatology and diagnosis of, 828.

Vineberg, Hiram N., acute cholecystitis in the puerperium; report of two cases; cholecystotomy; recovery, 532.

Violet, the perennial, 461.

Viper, lesions from the bite of a, treated by Calmette's serum, 70.

Virchow, a monument to, 303.

Visitation Boards of State Hospitals, abolishment of the, 702.

Visual function, relation of, to slanted handwriting, 601.

Vital statistics of Philadelphia, 263.

Vomiting, in children, intermittent hyperchlorhydria, as a cause of, 29; postoperative, 990; recurrent, 280; recurrent, in children, 348.

Von Ruck, Silvio, the heart and circulation in the prognosis and management of pulmonary tuberculosis, 851.

Vulva, fibroma of the, 307.

W.

Wainwright, John W., an emergency poisoning case, 719.

Waitzfelder, Edward, the treatment of cerebrospinal meningitis by diptheria antitoxin, 361.

Wakefield, Homer, a contribution to the etiology of malaria, and to the analysis of some relations of meteorology to chemical pathology, 81; cerebrospinal meningitis and the distribution of the blood, 746.

Walsh, Ferdinand C., acute posterior periurethral abscess, 617.

War, International Medical Association against, 622.

Washington, smoke nuisance in, 141.

Water drinking, abuse of, 38; influence of copious, 578.

Water supplies, purification and [illegible] of, 152; value of [illegible] of the public, 221.

Weil's disease, complicated by temporary tumors in the liver, 160.

Weir, James, Jr., responsibility in mental deformity, 816.

Welander's sack in lues, 946.
West, Jas. N., the prophylaxis and treatment of pyosalpinx, 969.
West Virginia State Medical Association, 902, 941.
White, Mark Johnston, pathological characters, diagnosis and epidemiology of bubonic plague, 121.
Whooping cough, treatment of, by antidiphtheritic serum, 671.
Widal reaction, the, 867; technique of the, 708.
Wiener, Alfred, conservative treatment of protracted cases of acute otitis media purulenta, with its complications, 534.
Willard Hospital dedicated, 302.
Williams, Charles Mallory, four cases of chancre of the lip, 290.
Windham County Medical Society, 783.
Wisconsin medical bill passed, 901.
Wisconsin State Medical Society, 979.
